Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. The Lumleian Lectures

ON

THE SEQUELS OF DISEASES.

Delivered before the Royal College of Physicians of London

BY SIR DYCE DUCKWORTH, M.D., LL.D. EDIN.,

FELLOW AND TREASURER OF THE COLLEGE; PHYSICIAN AND LECTURER ON MEDICINE, ST. BARTHOLOMEW'S HOSPITAL; AND HONORARY PHYSICIAN TO H.R.H. THE PRINCE OF WALES.

LECTURE II.[1]

Delivered on March 24th, 1896.

IN my last lecture I discussed at considerable length the varieties of sequels which may occur after enteric fever. We shall not find so much to claim our consideration in respect of many other diseases. I was led to dwell in detail on most of the residual disorders of enteric fever, because it appears to me probable that we have in this instance a typical example of the several consequences that may supervene upon the occurrence of specific and infectious diseases generally, one which may well serve to illustrate for us the intimate nature of, possibly, the majority of bacterio-toxic sequels. The task of tracing the hitherto hidden causes of sequels in a large class of diseases is made easier, by far, when we have to pursue the evolution and manifestations of microbic elements which are known and accurately recognised. We have not this knowledge as yet in respect of several of the infectious fevers, but we are now fully justified in forming opinions speculatively regarding a similar etiology for these, judging by the remarkable analogies that exist between those of which we have this knowledge and those of which, up till now, we have not. That we are still in ignorance of the exact and particular nature of the elements which generate the toxines of variola, varicella, scarlet fever, and some other diseases is somewhat remarkable when the researches of so many competent observers, pursued with untiring industry in all the great schools of medicine, is considered. We can hardly believe that these elements will much longer elude the scrutiny that is now focussed upon them. The subject is of paramount importance, and we may feel happy in the belief that no amount of sentimentalism or fanatical obloquy, either in this country or in the United States of America, will long delay the progress of knowledge in this direction. To those whose humane efforts are still curtailed and chastened in this country I would say, "*durate, et vosmet rebus servate secundis.*"[2]

I am indebted to my colleague Dr. Kanthack for knowledge of some recently recorded facts respecting the influence of typhoid bacilli. Dmockowski and Janowski have proved that these microbes, when injected into rabbits, are capable of producing suppuration, and the same occurs in dogs previously weakened by loss of blood or whose subcutaneous tissues have been first injured, also if these bacilli be injected under scars. The bacilli are found to wander to an inflamed or artificially predisposed site in from ten to twenty days after inoculation. These observers found typhoid bacilli in suppurative foci occurring after the fever, as in parotitis. They met with none escaping by the urine after the crisis of the fever.[3] In a case of ulcerative endocarditis which occurred in a patient suffering from typhoid fever, Dr. Kanthack found typhoid bacilli in the valvular excrescences. Janowski met with them in a case of fatal suppurative parotitis which followed seven weeks after the fever, when the Peyerian ulcerations were found quite healed. Wasserman of Berlin, as the result of his researches, believes that the complicating lesions of typhoid fever are usually due to mixed infections, as he found both typhoid bacilli, streptococci, and others in these conditions. These are the latest contributions to the subject, and they have the merit attaching to the researches of inquirers whose competence for the difficult task cannot anywhere be disputed.

Scarlet fever in severe cases has many complications and several sequels. Pleurisy is amongst the latter, and may be purulent from the first. Endocarditis is not infrequent, and some cases of valvular heart disease met with in later life are probably attributable to this. I shall presently discuss the intimate nature of this condition. Sero-fibrinous or purulent pericarditis may develop during convalescence, also myocarditis associated either with rheumatic or pyæmic conditions. Lymphadenitis may remain, become chronic, and prove but slowly amenable to treatment. Osler records an instance in which the neck remained enormously enlarged and surrounded by a mass of firm brawny glands for two years after an attack. Multiple neuritis, with progressive paralysis and muscular wasting, may occur. Cerebro-spinal insular sclerosis is alleged to have followed scarlet fever. The possibility of associated diphtheria must be borne in mind in some of the paralytic cases. Mania, idiocy,[4] insanity,[5] and melancholia have been recorded as sequels. Handford quotes Dr. Griffiths, of the Nottingham Fever Hospital, for the facts that in 1500 cases he met with two of chorea, one of disseminated sclerosis, and one of spastic paraplegia (probably functional) lasting only a few weeks. Slight hemiplegia (recoverable) has been noted, in all probability due to embolism or thrombosis. Optic neuritis may occur independently of organic cerebral change. Acute myelitis is noted amongst the sequels and epilepsy with more frequency than after any other acute infectious disorder. Nephritis is rather to be regarded as a phase of the disorder, or at least as a complication, and not a true sequel of scarlet fever. It is a definite form, attacking primarily the glomerular system of the kidney. Although it so commonly supervenes on apparent convalescence about the third or fourth week, and while desquamation is in progress over the body, I think it should be regarded as part of the original disease. It is as specific as the cutaneous exanthem, and its significance may be taken to indicate a late invasion of the kidneys by the microbic elements[6] or their toxines as yet not eliminated from the body, and possibly finding their way out by this emunctory channel. The occurrence of dropsy in some cases without albuminuria lends support to the old idea that the anasarca is probably a specific inflammatory exudation into the integuments and cavities. It is rare for such cases to recover ultimately without some degree of albuminuria.[7] Cirrhosis of the liver may be a sequel of scarlet fever. Barlow and others have noted this, and an interstitial overgrowth has been frequently observed in the livers of patients who have succumbed to the disease.[8] The sequels of otitis media suppurativa, perforation of the tympanic membrane, suppuration in the labyrinth, and necrosis of the petrous bone may be far-reaching and tedious.[9] Facial palsy, thrombosis of the lateral sinus, meningitis, and cerebral abscess may all ensue. Permanent deafness thus results. The tonsils may remain permanently enlarged. Goodhart records two cases of torticollis as a sequel. Suppurative peritonitis, enteritis, chronic diarrhœa, symmetrical gangrene, noma, and perforation of the palate have been noted, though rarely, as sequels. After enumerating such a grievous list of troubles as this it is interesting to know that in recent years this terrible pest has been generally present in a somewhat milder form than formerly, and that, therefore, the gravest sequels are rather less commonly met with than was the case five-and-twenty years ago. The disease has generally been of a severer type in this country than on the continent of Europe, and consequently is regarded with greater apprehension amongst ourselves. The arthritis which occurs in connexion with scarlet fever has been carefully studied only within a recent period. It has commonly been regarded as "rheumatic," or, at all events, as rheumatoid. Henoch proposes for it the term "scarlatinal synovitis." Goodhart believes that some cases are truly rheumatic, and others, such as suppurative arthritis, are pyæmic in nature. There is an apparent analogy between scarlatinal and gonorrhœal rheumatism (so-called), the former being regarded as a pyæmic infection from sores in the fauces. But articular

[9] Mr. Charles Parker has lately expressed the opinion that this sequel is probably due to the rapid development of post-nasal growths (adenomata), and considers it important to examine early for such and to remove them as soon as possible after convalescence.—Post-nasal Growths, 1894, p. 12.

Digitized by Google

disorder occurs in the course of scarlet fever *sine anginâ* when there is no source for infection from the fauces; and endocarditis may also be present in such cases. As indicated by Archibald Garrod, it is the association with arthritis of a series of other rheumatic phenomena which points to the truly rheumatic nature of the process, at least in some instances. Thus, endocarditis and pericarditis may occur, and chorea may supervene. Subcutaneous nodules may appear, also erythema nodosum and marginatum. With these facts before us, it is, I think, impossible to disregard the conclusion that scarlet fever strongly predisposes to rheumatism, and my belief is that the occurrence of it will be found most frequently, if not solely, in children of an inherited arthritic diathesis—an opinion of M. Peter in which I fully concur. This and other forms of zymotic disease may so test this habit of body as to awaken and reveal a rheumatic tendency hitherto dormant in the patient. I am indebted to Dr. Dickinson for his observation that the onset of true rheumatism following scarlet fever is especially apt to be succeeded by chorea, the latter, as I regard it, being a cerebral (cortical) manifestation of rheumatism. In my opinion, then, we may regard it as nearly certain, (1) that true rheumatic complications and sequels may be met with in scarlet fever and (2) that varities of arthritis, due to septic or pyæmic influence, may also occur. Of the latter, Dr. Ashby describes an early and late form, the latter occurring during desquamation. A purulent arthritis is rare.[10] We shall subsequently find that measles may act, as does scarlet fever in evoking rheumatic manifestations, or in preparing the way for them.

Measles is occasionally followed by chronic catarrh of the bronchi and lungs. Tuberculosis may become generalised, probably starting from a source in the bronchial glands or from patches of broncho-pneumonia. Enlarged tonsils and lympharia may remain long after the illness. Post-nasal glandular growths may occur as a sequel. Some observers mention the occurrence of endocarditis. I have never met with an instance of this. Rheumatic fever, however, sometimes supervenes on measles, and the latter condition appears to predispose to rheumatic manifestations in predisposed subjects. Endocarditis (rheumatic, not morbillous) may be one of these.[11] Cancrum oris and gangrene of the vulva have been noted. Destruction of nasal cartilages and necrosis of the upper or lower jaw may result in feeble children. A case of post-morbillous disseminated myelitis has been described by Dr. Barlow with rapidly spreading paralysis and a fatal issue on the eleventh day. Paraplegic symptoms due to polyneuritis have also been witnessed.[12] Dr. Dawson Williams has described an instance of false disseminated sclerosis of the cord as a sequel. Diarrhœa from intestinal catarrh and dysenteric symptoms due to colitis have been noted. The kidneys very rarely suffer. In 103 cases of acute nephritis collected by Dickinson measles was noted as an antecedent in only three cases. A condition of low health may long remain after an attack of measles, with a general vulnerability of most of the textures of the body. Dr. Fletcher Beach met with 11 cases of idiocy which followed on measles out of 2000 cases, and, *per contra*, Dr. Colman reports 2 cases of mentally backward children who both began to improve after measles. According to Barlow, infectious diseases are found to reinforce pre-existing nerve-lesions, and he gives as an instance the case of a child with infantile paralysis of the lower limbs who contracted measles, and after the paralysis had become general died comatose during the infective period. There has long been observed a relation between pertussis and measles. Dr. Charles West is of the opinion that the occurrence of any one of the eruptive fevers during the epidemic prevalence of another increases the liability to become affected with that which is epidemic, and that thus pertussis may supervene upon either measles or varicella. Dr. Goodhart noted the occurrence of pertussis fourteen times after measles in 305 cases of the latter. The same may be said of membranous laryngitis (diphtheria), which sometimes coexists with, or follows shortly after, an attack of measles. We have here an illustration of what may be termed a succession of diseases, one preparing the way, as it were, for another. The following series of illnesses in a family of three young children indicates fairly well what I mean—albeit the intervals between the several disorders were somewhat protracted. In the middle of June, 1895, all had measles. In November all had whooping-cough. Post-nasal adenomata occurred in one child as a sequel and were removed. In January, 1896, all these children had chicken-pox. Occurrences of this kind are by no means uncommon. No sequels are known after *rubeola* (German measles). Nephritis sometimes, but rarely, persists.

Variola is sometimes followed by peripheral neuritis, or a diffuse myelitis may cause paraplegia—ataxie-variolique. The pharynx may be paralysed alone or with other parts, as after diphtheria, from multiple spreading neuritis. Hemiplegia with aphasia sometimes follows encephalitis. Epilepsy, mania, and melancholia have been met with. Boils are not an infrequent sequel, and local gangrene may occur. Suppurative arthritis, epiphysitis, and necrosis of bone, also otitis media, may give trouble long after convalescence has been established. A grave degree of anæmia sometimes ensues after variola.

Parotitis in the milder forms has no sequels. In the severe forms meningitis is the gravest complication, and hemiplegia and coma may result. Such cases are generally fatal. Metastasis to the testis is rare before puberty, and atrophy of the organ may occur, with hindered development of it, if it occurs early in life. Albuminuria, uræmia, endocarditis, peripheral neuritis, also acute mania and insanity, have been recorded as sequels of mumps, but are happily most of them infrequent. Permanent deafness may result. Optic atrophy has been noted.[13] Arthritis has been observed to follow the subsidence of parotitis, and is probably one of the manifestations of the specific poison of this disease.[14] The pancreas appears to suffer in no degree from the specific toxine.

Pertussis is not seldom followed by chronic bronchitis with pulmonary emphysema. Hemiplegia is rare as a sequel. It may occur in a paroxysm of cough. The associated broncho-pneumonia is sometimes of tuberculous nature. Enlargement of bronchial glands is of frequent occurrence, and one or more of them, especially at the bifurcation of the trachea, may prove infected with caseated tubercle and lead to subsequent general tuberculosis. It is suggested that cardiac valvular disease may be induced by long-continued strain upon the heart and give rise to urgent symptoms in the future. Neither albuminuria nor glycosuria, if present, tends to persist, and the same may be affirmed in respect of the pulmonary emphysema which so commonly arises and of the interstitial emphysema which occasionally occurs, owing to rupture of the lung or trachea in a paroxysm of coughing. Pertussis is sometimes responsible for the supervention of post-nasal adenoid growths. Hæmorrhage into the adrenal bodies has been met with, due to the violence of the cough checking the flow of blood into the veins.[15]

Varicella has no true sequels save in respect of changes which may occur in the rash. Prurigo may result, so-called varicella prurigo (Hutchinson). Ecthymatous sores resembling pemphigus are sometimes met with. The vesicles may become gangrenous in delicate or tuberculous children, and the result is probably due to the supervention of extraneous microbic infection and not to the influence

[10] An excellent account of such cases is recorded by Bellingham Smith and Mary Sturge (Brit. Med. Jour., Nov. 16th, 1895, p. 1213). They met with nine examples of purulent arthritis in 5000 cases. The joints were attacked in the following order of frequency (in forty-five published cases) wrist and hand, elbow, ankle and joints of foot, knee, hip, and sterno-clavicular joint. The time of onset was from the third to the fifth week of the disease, chiefly early in the fourth week, or concomitantly with the onset of nephritis. Cardiac lesions were not commonly present. The arthritis varied from a simple serous to a purulent and destructive form. The simple form is generally called scarlatinal rheumatism. Streptococci were found in the serous effusions. Some cases were purulent from the first. The throat is the common source of infection, but empyema and peri-arthritic abscess may be the original focus. Epiphysitis was not met with, though it was common in the great Dublin epidemic of 1834–1842, according to Kennedy. Septic thrombosis of the jugular veins was not met with.

[11] Sansom records a case in which chorea with pericarditis and endocarditis developed during convalescence from measles. J. H. Hutchinson also records four cases in this connexion.—Transactions of the Royal Medical and Chirurgical Society, vol. lxxiv., 1891, p. 229.

[12] Bury states that sixty cases have been described (up to 1893) of paralyses of cerebral or spinal origin developing during the course of, or in early convalescence from, measles. Some of these were probably due to multiple neuritis.

[13] Dr. Caleb Parry records a case of orchitis following parotitis in which obstinate suppression (? retention) of urine occurred long requiring the use of the catheter. Cases of secondary parotitis are of extreme interest. Stephen Paget and others have well described them. They do not, however, concern us in these lectures, inasmuch as they may all be classed as complications rather than sequels of disease. I may refer the reader to an excellent essay on the subject by Dr. Hawthorne of Glasgow, published in the Glasgow Medical Journal, July, 1895, with a complete bibliography of the subject.

[14] Treatise on Rheumatism: A. Garrod, 1890, p. 186.

directly of varicella poison. Like the eruptive fevers, varicella may be followed by pertussis, a lowered condition of health thus induced paving the way for fresh infection with increased susceptibility to it.

Influenza.—The sequels of this disorder have only been studied with care in the course of the epidemics which have prevailed in the last seven years. They escaped the attention of the older observers. They are very numerous. It may be fairly affirmed that many of the gravest characters of the malady occur after the acute stage has passed away and when convalescence is apparently assured. I think there has possibly been exaggeration in respect of some of the alleged sequels of influenza; still they are, as I have said, numerous. The general asthenic type of the disease is well recognised. The enfeebled mental and bodily states left behind it have been forcibly and sadly brought home to most of us of late, both in our own persons and in our patients and friends. Recognising the fact that each epidemic is signalised by a dominant form for the most part, we may discuss the particular sequels attending, first, the thoracic, secondly, the gastro-intestinal, and, thirdly, the nervous varieties of influenza. The personal factor comes in here strongly in respect of each individual affected, and, as has been said, "each patient convalesces according to his temperament" and, no less, I would say, his diathesis. Nearly sixty years ago Sir Henry Holland noted the long persisting influence of this disease upon the constitution as a remarkable feature; also the variation of parts affected in different individuals or at different periods in its progress. In respect of sequels ensuing on the thoracic forms we may note the prolonged course of the peculiar broncho-pneumonia so often fatal to the weakly and the aged in its earlier stage. Next, the onset of tuberculosis. Abscess of the lung has been several times met with supervening on pneumonia, and Pfeiffer's bacillus has been found in the yellowish brown sputa expectorated from it, together with elastic fibres from the lung. Hitzig[16] records a case in which careful examination proved the matter from the abscess to be free from streptococci, staphylococci, and from tubercle bacilli, and to contain only influenzal bacilli. Pleurisy is common and empyema may result. The heart is often severely affected. Great weakness of the organ is common; arhythmia, bradycardia, tachycardia, and pseudo-anginal attacks with dilatation, may occur long after the illness. Pericarditis and endocarditis are but rarely met with. Vertigo is a very frequent symptom, a tendency to it persisting for months after an attack. The gastro-intestinal variety of influenza may lead subsequently to vomiting, simple catarrhal jaundice, chronic gastro-intestinal catarrh, diarrhœa, or constipation, with marked nervous depression. The nervous variety is apt to lead up to many subsequent troubles. A rapid denutrition of nerve centres is more or less common in all cases presenting any severity in the early stages. Neurasthenia may prevail for one or two years subsequently. Polyneuritis is a common sequel. The arms may be paralysed, with both motory and sensory disturbance, and wrist-drop may occur; moreover, the same process may occur over large areas. Neuritis may involve cranial and other nerves locally. Encephalitis, myelitis, sclerosis of various tracts of the spinal cord, neuralgia, especially the intercostal variety, conjunctivitis, iritis, otitis media, mastoid abscess, malignant endocarditis, parotitis, orchitis, and lymphadenoma, with many other affections, have been noted amongst sequels in various recent epidemics in all parts of the world. Somnolence, or extraordinary drowsiness, with hebetude, is a noteworthy feature. Headache, vomiting, and various mental disorders may occur. Melancholia leading to suicide is by no means uncommon. Mental incapacity long remains, and many patients affected in middle life tell of inability for efforts, mental and bodily, that were easy to them previously. They feel many years older in all respects.[17] The natural level of health may never be regained, or not fully re-established, for two or three years after a severe attack. Abscess of the brain has been several times noted as a sequel, also simple lepto-meningitis. Dr. Harry Campbell has recorded a case in which a young man, a victim of hemicrania, lost this tendency after an attack of influenza. Mental affections may also sometimes subside after an attack. The sequels of this disease are doubtless often very varied and often extraordinary. A medical friend of mine has been unable to take coffee since he suffered from a severe attack in February, 1895, without feeling considerable cardiac discomfort, although there was no arhythmia and the heart sounds remained normal. In his case, too, and in another there remained for months subsequently a liability to paroxysms of low temperature, with extreme chilliness and distressing sensations, observations made in the mouth, axillæ, and rectum recording a temperature of only 96° F. Such attacks continued to occur once in every eight or ten days and not unfrequently in the night. (Nothing afforded so much relief as an ounce of whisky taken as hot toddy.)

Influenza, in common with other infectious diseases, distinctly appears to predispose to the onset of other diseases. The lowered vitality induced by the primary malady leaves the patient a more ready prey to the attack of any other he may be exposed to. Sir William Broadbent has expressed the opinion that an attack of influenza may in this way determine the outbreak of enteric fever, the pyrexia of the former running on into the latter, so that the new malady may appear to be, as it were, a prolongation of influenzal fever. Or a distinct interval may elapse between the one disorder and the other. Translated into the language of to-day, we may substitute for the term "lowered vitality" a condition of the solids and fluids of the body in respect of their powers of resistance to invasion by specific toxines which is unequal to the struggle between them and the infection. We have already noted instances of a like kind in the cases of measles, varicella, and pertussis. It is also conceived by Broadbent and others that germs of diseases may lie latent in the body and remain inoperative till the resistance of the host is impaired by some circumstance, such as infectious or other illness, or traumatism, which forthwith liberates the latent germs with the consecutive onset of a fresh ailment. The occurrence so frequently of tuberculosis after injuries and infectious fevers may possibly be explained in this way, also the development of tertiary syphilitic disorders.

Relapses of influenza are commonly met with and may occur several times at fairly long intervals after the primary infection, and long after the original epidemic has passed away. We may doubt the occurrence of fresh infection from without, as by sporadic influence, in many such instances, and I think we may consider as probable a view of this matter for which I am indebted to our registrar, Dr. Edward Liveing. He conceives it to be not unlikely that the toxine of influenza may act very much as does that of malaria, leaving behind it residues of specific infective matter, which wake up into activity from time to time, and induce fresh outbursts of the disease in response to any conditions which temporarily lower the general vitality of the body. We may thus regard such relapses as evidence of sequels of the direct residual class. I have experience of cases in which four or five attacks have occurred within two or three years and at varying intervals. The conditions in respect of symptoms, type of pyrexia, and general character leave no doubt as to the true nature of the disorder, and intelligent patients, in three cases in the persons of well-known members of our profession, have recognised only too well the specific qualities of it.

Acute bronchocele has been several times observed to follow influenza. One lobe may become greatly enlarged and give rise to dyspnœa or orthopnœa, with a fluctuating tumour. Incisions give exit to viscid fluid with relief to the symptoms, but the discharge may continue to flow for months—thirteen months in a case recorded by Dr. Browne of Alderley Edge.[18] In another case there remained enlargement of the gland for eighteen months, acute inflammation having begun three days after the influenzal temperature fell to normal. One of the most remarkable cases I have seen occurred in a man aged sixty-eight years, brought to me by Dr. Elliott of Chester, in whom great wasting had occurred in the pectoral muscles. This followed an attack of influenza nine months previously. Twenty-eight pounds weight had been lost during that time. The ribs were plainly visible: There was marked difficulty of inspiration and the upper portion of the chest hardly moved. There was no myoidema. The brachial muscles were soft but those of the lower limbs were firm.

[16] Munchener Medicinische Wochenschrift, Aug. 27th, 1895.

[17] One of my patients aged sixty-eight years, a former athlete at Cambridge, stated that he felt like a man of thirty-five till he had influenza; afterwards he felt like a man of seventy.

[18] Brit. Med. Jour., June 8th, 1895, and references to other cases May 2nd, 1895.

There was general weakness and early fatigue on walking. Improvement slowly followed treatment by massage, warm douching, and dosage with strychnine, phosphorus, and arsenic. This man was at one time apparently in peril from respiratory difficulties. There was evidently some focal myelitis in the cervical portion of the cord. My colleague, Dr. Lewis Jones, has given me particulars of a case in which wasting of the muscles of one buttock followed after an attack of influenza. Recovery ensued after treatment. Bladder troubles may set in and persist after an attack. Diabetes has been several times observed as a sequel.[19] Arthritis and multiple synovitis sometimes follow influenza. At the outset of many cases it is sometimes difficult to be sure that rheumatic fever is not in progress. There may be pains in the joints and pyrexia. The two disorders may even occur together and lead to a very grave condition owing to carditis. Cases have been carefully observed in which symptoms of myelitis, involving several tracts in the cord as well as the cornua, have led to arthritis or true spinal arthropathy. Dr. Sansom has directed attention to such cases, and has carefully studied them.[20] He has shown that there may be both affection of the cord and of the peripheral nerves in such instances. In a case he relates at length there was polyarthritis and symptoms pointing to disease of the anterolateral columns, muscular spasms, and contractions, motor paralysis and muscular wasting, also sensory changes, incoördination and delayed transmission of thermic and other impressions. No pyrexia was present. The subject was a woman of rheumatic proclivity, but Dr. Sansom found no ordinary symptoms of rheumatic fever. The illness began four months after a confinement and was clearly influenza, and many of the above symptoms were present on her admission to hospital. She left benefited, but returned in two months' time with arthritis of the left knee newly set up. This was six months after the attack of influenza. An almost perfect recovery from all the symptoms ensued, and this is an encouraging fact to note, since it relates to the prognosis of nearly all such grave conditions following influenza. My colleague, Mr. Howard Marsh, has recorded several examples of arthritis of this nature.[21] He has found the hip-joint most often attacked. Synovitis first sets in, with stiffness and swelling. Muscular wasting soon follows. Severe sciatica occurred in one such case. There was fever, with a temperature of 102° F., in one case. The symptoms usually subside in two months' time. In one instance the disorder followed six months, and in another seven months, after attacks of influenza. The conditions appear to simulate tuberculous disease of the joints, but the prognosis is generally satisfactory. Mr. Jennings has recorded two cases in which influenza appeared to cause reopening of old wounds in the skulls of miners which led to abscesses and fatal results.[22]

Were I to enter at length in laying before you an account of the sequels of influenza as set forth in the special literature on the subject during the last five years the whole time allotted to me would not suffice for the purpose. For a minute account of these I would refer you to the second edition of Dr. Althaus's work on influenza.[23] He records instances of every variety of complications and sequels with an elaboration into which I cannot attempt to follow him. They amount to at least sixty in number, and this writer has calculated that varieties of sequels may be looked for in about 20 per cent. of all cases. After perusal of this work one must not feel surprised to meet with almost every known malady as a sequel of influenza, and the prospect is, indeed, almost overwhelming. At this moment, however, I may perhaps venture to say, *Satis est, quod sufficit.*

Erysipelas.—Mental disturbance is rarely a sequel, but mania and delusions may occur on the subsidence of local symptoms. Recovery is the rule. Palatine and laryngeal abductor palsy followed one case complicated with pneumonia. The laryngeal paralysis necessitated tracheotomy and was permanent.[24] Bradycardia has been noted. Disappearance of chronic skin diseases has sometimes occurred after an attack of erysipelas, such as eczema or lupus, and sarcomata have also been similarly found to subside. Treatment for the latter has accordingly been practised of late by introducing cultivations of toxine from erysipelatous textures into the growths, so far, I believe, with no very satisfactory results.[25] The tendency to recurrence of erysipelas, which has hitherto been explained by fresh infection with the specific poison, is now believed to be due to the survival of germs (Fehleisen's streptococcus) which have remained latent in the tissues, and are provoked into activity by the irritation of traumatism or by exposure to undue heat or cold. Patients of gouty tendency were formerly believed to be especially liable to attacks of erysipelas; Caleb Parry and James Gregory in particular directed attention to this fact, but I am not prepared to confirm their statement so far as my own experience guides me. Traumatism in any degree predisposes to erysipelas, with or without breach of surface, in the former case by admitting specific germs, and in the latter, probably, by affording a *locus minoris resistentiæ* wherein those that may be dormant in the system may become active and potential. Malignant endocarditis has been observed, though rarely, as a sequel; and streptococci have been found in the aqueous humour in a case of cyclitis following erysipelas.

Diphtheria.—The sequels of this disease are so remarkable and at times so serious that they have attracted close attention. I cannot discover evidence that these very obvious consequences were witnessed or described by the older physicians. But since diphtheria became endemic in this country in 1855 they have not failed to be noted and recognised as depending upon the original malady. The albuminuria which is so common during the active stage of the disease usually passes off leaving no trace of nephritis. But it may persist for two months subsequently. Dropsy is of very rare occurrence in this relation. Parenchymatous nephritis has been noted, but it is open to question whether the disorder thus complicated is not scarlet-fever rather than diphtheria. It is certainly very rare. The albuminuria is probably of toxic origin and so far specific. The gravest sequels are paralytic conditions, and the latest researches respecting them plainly indicate that they are due to a toxic neuritis which may be widely spread. These paralyses occur in from 10 to 20 per cent. of all cases. They occur usually in from two to six weeks after the onset of diphtheria and are commonly more marked in adults than in children. They may be local or general. Of the former we note palatal and pharyngeal palsies, strabismus, ptosis, ophthalmoplegia interna, and facial palsy. With some of these may be associated symptoms of general paresis or actual palsy. The general paralyses are of the same nature as the local, and are due to polyneuritis of toxic nature with loss of reflexes. The vagus nerve is especially apt to suffer, and the evidence of this is afforded by great cardiac weakness with bradycardia or tachycardia, or by fatal syncope. Vomiting may be troublesome, and may precede the cardiac symptoms. Loss of knee-jerk may sometimes be the only sign of nervous sequels. This is, however, always a symptom indicating gravity and demanding vigilance in any case. The sphincters, as a rule, are unaffected. With due care in treatment and an intelligent appreciation of the special dangers of such cases the prognosis is on the whole good. Perfect recovery may be anticipated within three or four months. Fagge records a case in which signs of palatal palsy had remained for four years after diphtheria. Rarely there may persist some enfeeblement of muscles in the limbs. I have a general impression, although unsupported by any figures in proof of it, that the nervous sequels of this disease have been less frequently met with since treatment by antitoxin has been employed. We are fairly justified in anticipating that such may be the case. Recent researches of Sidney Martin and Kanthack plainly indicate that the diphtheria bacillary toxine induces a specific and spreading neuritis in animals, and hence we are justified in the assumption that a precisely similar process occurs in the human subject. According to the observers just mentioned the neuritis of diphtheria is primary, the sheath of Schwann being first attacked and the axis-cylinder of the nerve subsequently. Kanthack has found the bacilli in the spleen and in the lungs. Dr. Pasteur has directed attention of late to the association of respiratory paralysis with cardiopulmonary symptoms in diphtheritic multiple paralysis.[26] In a series of 64 cases of diphtheritic paralysis serious cardiopulmonary "crises" occurred in 20, and in 17 of these there

was associated paralysis of the diaphragm. Most of them occurred between the ages of two and six years. Dr. Pasteur relates the particulars of 32 cases in which the diaphragm and intercostal muscles were more or less involved and gives an admirable and suggestive *résumé* of them. He makes a distinction between cases in which the disorder of the phrenic and intercostal nerves is peripheral and those in which the phrenic nerves are involved centrally or near to their nuclear (bulbar) origin. In the former the diaphragmatic paralysis may develop insidiously and is altogether less grave, in the latter it may come on suddenly, in an acute crisis, with symptoms of dyspnœa and asphyxia, also with transient pyrexia and vomiting. Such cases are almost certainly fatal. Phrenic or intercostal palsy appears, according to Dr. Pasteur, to determine collapse of the adjacent portions of the lung and especially of the base of the right lung.

As indicating the remarkable advance made in pathological and clinical study in quite recent times I may recall here a passage taken from Sir Thomas Watson's classical lectures to be found in the last edition, issued just twenty-five years ago.[27] He remarks: "All these sequelæ are significant of blood-poisoning. We cannot suppose that the nervous symptoms—transient and wandering as they often are—can have their cause in any grave or material damage in the nervous centres. They denote, I presume, disturbed nutrition of the tissues from imperfect or altered conditions of its circulating blood." Watson was right in his belief that the nerve-centres were not involved, but the whole subject of neuritis in its many forms now constitutes a new chapter in medicine, one for which few materials existed in Watson's time, and those the careful observations of Chomel and of Graves, now sixty-eight years old, which might have, but somehow did not, set inquirers upon the track to discover peripheral neuritis.

As indicating how the supervention of a new infection may prepare the way for fresh outbursts of diphtherial disease I may quote the case, recorded by Dr. Hayward, of a child who, while recovering from diphtheria, was attacked with measles. On the invasion of the latter there was a renewed activity of the lingering diphtherial bacilli with a reformation of faucial membrane. We have already noted how similar troubles may ensue when the vitality is lowered in cases of influenza, measles, varicella, and pertussis. Disorders of the mucous membrane of the nose and otitis are to be included amongst the occasional sequels of diphtheria, also post-nasal adenoid growths. It is probable, if not certain, that some of the post-diphtherial sequels are due, as in other cases, to the results of mixed bacillary infections. The commonly associated broncho-pneumonia has been proved by Kanthack to be due to specific bacillary invasion of the lung. Malignant endocarditis is sometimes a sequel of diphtheria.

Malarial fevers.—The sequels of these present several problems upon which much light has been recently shed since the discovery of their intimate nature and their dependence upon the several phases of the life of certain hæmatozoa or sporozoa. We have the fact that, according to the degree of impregnation of the system by these parasitic bodies, there remains for long, sometimes for life, a tendency to recurrence of specific pyretic processes under certain provocations, and not seldom the establishment of what is well known as malarial cachexia. A subject of the latter condition may resist all treatment and die of anæmia or from hæmorrhage. The liver and spleen are commonly, but not always, enlarged. Paraplegia, sometimes spastic, has occasionally been noted. Intermittent paralyses, intermittent aphasia, cramps, hyperæsthesia, anæsthesia, articular pain and swellings, œdema, and urticaria very specially have been noted to follow malarial impregnation, all of these impressed with a periodic or intermittent character. These strange conditions we now explain by reference to the particular organs infested from time to time, and yielding manifestations of the development of the specific blood-parasite. Saccharine diabetes is sometimes distinctly traceable to previous malarious impregnation. Neuralgia in various forms has been noted as a sequel affecting intercostal, occipital, sciatic, and testicular branches. The supra-orbital branch of the fifth cranial nerve is especially liable to be thus involved, the condition being sometimes described as "brow ague." We have to be careful in assigning to malarial influence any conditions of a periodic or intermittent character which may not certainly be connected with submission, at some time or other, to exposure to specific hæmatozoal infection. It is a character of all neuralgias to be paroxysmal and intermittent, even, as shown by Weir Mitchell, when of traumatic origin. But it appears certain that the effects of malarial impregnation may for many years induce a condition which modifies the course and characters of other ailments. Thus, according to Fayrer, "periodicity complicates all diseases in India." A chill induced in any way may awaken activity of febrile symptoms many years after subjection to malarial influence. Neurasthenia and spasmodic asthma are amongst the protean manifestations recognised in this relation, also intermittent torticollis, and a rebellious form of hiccough. This peculiar latency of malarial influence has now to be considered with reference to the modern doctrines held as to the nature of the disease. It is believed that the malarial germs are not absolutely destroyed, but only rendered impotent or latent by drugs held in repute for cure, such as quinine and arsenic. Improved general health of the patient appears to render the hæmatozoa latent for a time. New forms of illness may induce fresh activity of the hitherto latent germs. According to Manson, the causes of latency are various even for the same micro-organism. It has been proved that individuals may become immunised to the toxines of bacilli although the microbes may continue to exist and grow. The latter may thus apparently remain latent or dormant, englobed in cells or prevented by a barrier of cells from gaining access to the body (Washbourn). In malarial infection there is often evidence of the presence of varieties of hæmatozoa, or admixture of parasites, each of which may cause various types of fever. Quinine has more power in destroying some of these than others. It appears certain that some of these bodies undergo development in various organs of the body, especially the liver, spleen, intestinal mucous membrane, brain, and bone-marrow. Many of the symptoms appear to depend upon the organ selected for their accumulation and sporulation. The blood is most impregnated at the beginning of a paroxysm of fever, and least so in the apyretic intervals. As Manson has pointed out, the principal acts in the drama in pernicious cases are played out in the viscera, whence, at intervals, swarms of parasites are embolically shed into the circulation, producing the varied symptoms of malarial pyrexia. We may account for the lingering tendency to recurrence of paroxysms by supposing that the specific hæmatozoa in a given case have never been quite annihilated, but have remained latent or quiescent, locked up, as it were, in some viscus or tissues of the body, and only set free by the onset of some general disturbance which lowers the vitality and resistance of the patient. I think we may fairly anticipate that some absolute proof in support of this conception will be presented to us before the lapse of many years.

Dengue may be followed by troublesome enlargement of the lympharia for many weeks after the illness, and the same mental and physical prostration may long remain after an attack, as is witnessed after influenza.

Epidemic cerebro-spinal meningitis may have for sequels persistent vomiting and sometimes a spinal arthropathy, even purulent arthritis. Optic neuritis with atrophy and blindness has been noted, also otitis interna with deafness, leading in children to deaf-mutism. Headache may persist for months or years. Chronic hydrocephalus, imbecility, and aphasia may occur. Peripheral neuritis of some of the cranial or spinal nerves has been observed.

Several sequels are recognised as results of *Dysentery*. A form of arthritis sometimes sets in, perhaps a month after recovery, rheumatoid but not rheumatic, possibly akin to gonorrhœal or infective arthritis. Several joints are commonly involved, but there is not much pain. These troubles generally pass away within a few weeks or months, and have been observed to supervene in milder rather than in severer cases of dysentery. The swelling may be very great. No sweating or cardiac complication has been noted, and the degree of pyrexia is usually mild. Chronic nephritis may follow an attack of dysentery. Neuritis leading to paraplegia has been noted. Chronic dyspepsia, irritability of the bowels, and a cachectic condition, with wasting and anæmia, may ensue after severe and repeated attacks. This state is doubtless due to destruction of large tracts of the mucous coat of the colon, which are replaced by scar-tissue of no functional activity.

Cholera.—Convalescence is sometimes protracted. Anæmia may long remain, and the menstrual functions may cease

[27] Lectures on the Principles and Practice of Physic. Fifth edition, 1871, p. 895.

Digitized by Google

for many months. Tetany may affect all the limbs, and may spread to the trunk and involve the glottis, causing suffocation. Phlegmonous furunculosis, sometimes ending in gangrene, may supervene, and this condition has been found associated with glycosuria. They are not improbably due to secondary infections from the intestinal surface. Dyspepsia and rebellious diarrhœa may persist after an attack. Bronchitis, pleurisy, pneumonia, suppurative parotitis, gangrene of the extremities, and ulceration of the cornea have all been noted, also diphtheritic inflammation of the fauces and genitalia. Paralytic sequels have been met with, also mental disturbance. One attack is not prophylactic against a second one.

Oriental or bubonic plague.—Some sequels have been noted in patients who have suffered and recovered from this specific and most contagious disease. Furuncles, dropsy, partial paralyses, and mental disturbances are amongst the most frequent. The fact that Kitasato's bacillus has been found in the blood, glands, and viscera, affords an explanation of such consequences and leads to the belief that they depend, like those of enteric and some other fevers, upon microbic residues, with, possibly, additional and fresh (mixed) infections of other, though non-specific, toxic elements.

In my next lecture I shall discuss the sequels of syphilis.

A Presidential Address

ON THE

PRESENT AND PROSPECTIVE CONDITIONS OF MEDICAL EDUCATION.

Delivered at the Fourth Session of the Inter-colonial Medical Congress of Australasia at Dunedin, New Zealand, on Feb. 3rd, 1896,

BY FERDINAND CAMPION BATCHELOR, M.D. DURH., L.R.C.P. EDIN., M.R.C.S. ENG.,

FELLOW OF THE OBSTETRICAL SOCIETY OF LONDON, VICE-PRESIDENT OF THE BRITISH GYNÆCOLOGICAL SOCIETY, LECTURER ON MIDWIFERY AND GYNÆCOLOGY AT THE OTAGO SCHOOL OF MEDICINE.

[THE President commenced by thanking the members of the Congress for the honour they had conferred upon him in electing him as their president and then briefly referred to the place of medicine among the exact sciences. He reviewed the progress that had been made, first, in regard to certain instruments of precision, such as the clinical thermometer, the stethoscope, the sphygmograph, and the microscope, and then passed on to some of the more striking advances within the last twenty-five years of chemistry in its relation to medicine. The progress of experimental physiology was the next topic dealt with, and the progress of bacteriology and the antitoxin investigations were ably passed in review. Dealing with the scheme of professional study the President said:—]

In the face of these vast changes, what corresponding advance may there be discerned in the education provided to meet the consequent new conditions? Practically, a survey of the range of medical education throughout the empire shows that there has been very little change in the education we provide at the earlier stages of a young man's course. The conditions of entrance into professional study vary in a remarkable degree. While the Universities of Oxford and Dublin do not confer a medical degree unless the candidate has previously graduated in arts, there are many examining bodies which ask for no further proof of preliminary education in literature and science except that of a common leaving certificate such as a schoolboy may win in England by way of the local examinations or in Australasia by a somewhat low-graded matriculation. Now ever since 1873, the year of Forster's Act, there has been in Great Britain and throughout the empire a fairly satisfactory system of primary education, graded into standards of which the highest is usually passed by children at the age of thirteen. Three years' further study at a respectable high school on the lines of a liberal education should bring a boy to the level of a sound test of a higher quality, I think, than our matriculation examination here provides. Then should ensue two years' study of special scientific subjects preparatory to the strict professional education, which should continue for at least four years further. What, however, is the case with regard to this preparatory study—the belt of ground occupying the space between leaving school and beginning professional education? I venture to think that this most important detail of junior professional work remains in the most chaotic and unsatisfactory condition. The medical man of the immediate future should, above all things, aim at being scientific in his habits of thought and methods of practice. He should have acquired the eye of science, the ear of science, the hand of science, the judgment of science; he should know that he really sees what he is looking at, hears what he is listening for, and touches with discrimination what he handles. He should be capable of judging clearly in his diagnosis and be in the habit of looking for clearly recorded phenomena on which to base his ultimate conclusion; his practice and his theory should be mutually helpful. He should be able, not merely in a humble way, to follow the great pathologists of the hour in his application of their work, but also to appreciate their methods and their labours, if not actually ambitious to emulate them. As fast as medicine continues to travel out of the region of empiricism, so will it be needful for empirical modes of thought and practice to be laid aside. We may say, after the great German poet, "More light"—that is, "more science, more science"—for to us science is light. In my own time the apprenticeship system as a training of young aspirants to the medical profession was still in vogue. It was thought that after registration the best way a young man could commence his work was to enter what might be called a medical man's dispensary. Readers of "Middlemarch," that most faithful picture of medical life in England fifty years ago, will recollect how justly a medical man was then identified with his dispensary. Compounding drugs, extracting teeth, bleeding, dressing of small wounds and sores, with occasional clinical practice among the poor amidst the most adverse circumstances—these were the conditions which were held to seriously incline a young man to his professional career. I believe there are many respectable opinions still expressed in approbation of this older style of medical training. It produced good men; why should it not continue to produce good men? Doubtless, for the knowledge than accessible, the training was good and sound. Most work was empirical, and it was surely of some advantage to be associated with an empiric of great experience and possibly considerable success. So much depended upon observation of more or less transitory significance that in the absence of scientific or theoretical principles the methods of actual practice were, doubtless, as good as might be got. However, I am inclined to think that if anyone still advocates the old apprenticeship plan as suitable to modern requirements, such a man has allowed the tide to run past him; he has failed to note the signs of the times, and does not observe that exact science has advanced, is advancing, and will continue to advance in every department of our work, and that the need for increased opportunities for scientific training become for our junior students more and more impressive. It would be, in my opinion, most beneficial to have one standard of junior work fixed by the General Medical Council—a course covering at least two years from matriculation. About the matriculation itself, except that it should be a fairly exact test examination for high and grammar schools so as to give boys a respectable leaving certificate—about this I say nothing, but I am strongly of opinion that for two years subsequently, if not more than two years, the whole time should be given up to purely scientific study. It ought to be noted that with remarkable prescience the senate of the University of London have for many years past insisted upon a scientific intermediate between matriculation and the first professional examination. This preliminary scientific examination is of such a kind that it practically enforces two years' work at physics, chemistry, and general biology, and the candidate is not eligible for the final M.B. examination until four years after his success in the preliminary scientific examination. I do not now argue whether it is desirable for us to aim at a standard so rigorously high, because I do not think, in our conditions in Australasia, it is possible to command the supply of men willing to undergo such severely exacting tests; but it seems to me that the first two years of the medical curriculum of the University of Sydney is quite good enough for our wants at the present

Digitized by Google

stage of our population and requirements. In the University of Sydney professional subjects do not come under the student's notice until his third year, during which year he is limited to materia medica and therapeutics. His professional studies do not commence until his fourth year, while chemistry, physics, anatomy, physiology, and biology form the whole of his studies for the first two years. Thus in this admirable course full provision is made for the scientific habits of thought and method for which I am pleading—habits which, if once acquired, hasten amazingly all subsequent progress and make a man more apt to learn for all the rest of his days. It seems to me that what we have a right to demand is that our junior men shall be trained in scientific lines. It is the manner of their training that is paramount; the matter of their training, however important of itself, is really of subsidiary interest. In making this reference to the University of Sydney I desire to record my respect for the work done in the other medical schools in Melbourne, Adelaide, and in our own. I have visited each centre of medical work quite recently and have endeavoured to form some estimate of the value of each. I am convinced that according to the standards for which I am contending that the University of Sydney approaches most closely to my ideal. As to the rest of the empire, the condition of things is still most disorderly. It was no part of my original design to include in this address the subject of professional education. I had been, in the main, contending that the rapid and wide extension of scientific knowledge has not been yet overtaken by a proper readjustment of the subjects of study for our junior students, to which argument has been added a word or two of suggestion looking towards reform.

But there is a point connected with our colonial system of superior professional education which should not be omitted. I refer to the point of contact between our hospitals and our medical schools. In Great Britain many of the hospitals are of a respectable antiquity, and are older by many generations than the schools attached to them; it is not, therefore, true matter of surprise that these hospitals, hoary with age, find themselves unequally matched with the child that has become almost their rival, and that traditions, vested rights, and antiquated regulations should from time to time cause a harsh note of discord to be struck as between hospital and school.

In Australasia, where every institution is young—where hospitals, instead of being maintained by endowments and voluntary contributions, are for the most part supported directly out of rates or taxes, while the medical schools have been called into being by universities or Acts of Parliament, and are principally maintained out of endowments or rates and taxes,—in such a case it ought to be that each is the handmaid of the other; that the home of suffering and the message of relief should be united in the close ties appropriate to the necessities of each; that the science of healing should profit directly and progress directly where its work is subjected to the severest tests; that, in fact, methods in healing should be identified with the science of healing, that the teaching body should be identified with the executive body in any hospital where there is a medical school. What, however, do we find to be the case? With one exception, to which I shall advert later, our hospitals are under a control which has nothing to do with any university or any collegiate board. As a matter of fact the managers of the hospitals know little, and would at times seem to care less, about the medical school, so that the clinical teachers in Australasian hospitals are in no way responsible to the university councils, which in their turn are responsible to the public for the character and results of the teaching offered to the students. I take the worst case I know of, perhaps the worst in the British Empire, in which the interests of the public, of the patients, and of the profession are sacrificed to collateral questions or subordinated to side issues. In Melbourne every third year the whole medical staff is exposed to the ordeal of a public election; the board of management, much less the University Senate, is allowed no voice and no control; the election is in the hands of the subscribers; hence when the fateful day arrives all the features of a contested election become prominent—election tickets are put out and election devices prevail, cards soliciting your interest and vote for Dr. D— — and Mr. C—— are found in hotels and bars and railway stations and in cabs. Dr. D—— and Mr. C—— are for the next three years to be entrusted with thousands of pain-racked men and women, the clinical teaching by the bedside, and the ethical training of aspirants to our profession. To secure the position, so responsible, so admirable, they are driven to have recourse to the usual mischievous dodges, practices, and traps of an election contest. Surely it is a scandal that in any British community, much less in a community which takes pride in its progressive spirit, such a pernicious system should survive for an hour. In Adelaide difficulties arise out of a system not so mischievous, but radically bad; the university has little control in hospital affairs—in fact, only one member of the University Senate has a seat on the hospital board. It so happens that in Adelaide matters have worked with reasonable smoothness because the Government in the past have taken care to appoint to the board men known to have some interest in, and sympathy with, the medical school, but there is no guarantee for permanency in the constitution of things, which seem to be based upon an unreasonable jealousy of the profession or that wider and deeper impatience and distrust of learning—a sentiment noticeable and operative in every democratic community. In New Zealand a similar state of affairs obtains, modified in its features, but powerful enough to have occasionally imperilled the very existence of the medical school. Our survival is simply owing to the enlightened good sense and moderation of the men who have happened to have been elected to the board of management during the past few years, and who retain their position on that board in virtue of considerations entirely other than those of the interest of our school. I do not think our profession should escape its share of blame for these results. In a town possessing a medical school it is clear that of our professional men some must be excluded from the university appointments, while others win them; the former, being more numerous as well as unsuccessful, coöperate strenuously to oppose the university teachers should they make any claim for priority in the distribution of hospital appointments. The consequence of all these combined sentiments and customs is to dislocate and derange our teaching, to render clinical instruction of relatively weaker value, to attenuate the responsibility and to sacrifice the future of our profession to the jealousies and bickerings of the hour. The university, however, now stands clear of animadversions such as these. The difficulties between the university and the board of the Sydney Infirmary were felt to be so great and the prospects of a satisfactory solution so remote that it was in a great measure at any rate to obviate these troubles that the Prince Alfred Hospital owes its foundation. The relations between this hospital and the university senate are of a satisfactory character—a fact which, added to what I hold to be the superior arrangements of their course of study, should go far to see the Sydney school the most efficient and most useful of all the Australasian schools of medicine. Surely here is a point upon which we might close up shoulder to shoulder and, in view of the requirements of the age, insist that for the public good it is requisite that our students should be sent out fully armed to cope with the increasing demands upon their knowledge, their skill, and their judgment, and that the bodies responsible for the proper education of our students should have a controlling voice in the appointment of their teachers and in those details of hospital management which directly concern the education of their students. I have digressed a little upon this matter before bringing my address to a close, because until these barriers are removed our progress will be both painful and slow.

Passing, however, from considerations that are local and must be temporary, I would desire indulgence for a few words dealing with more general notions connected with our profession. It has been finely said that the most valuable asset of a State or of a nation is the people. A healthy mind in a healthy body is the gist of the old Roman prayer, a sentiment obviously applicable in the widest sense to the condition of a people. The joint prosperity and advancement of a nation depend upon its physical and moral health, on that well-balanced condition of the human framework which interprets and affects all that belongs to thought and action. How far morality depends upon health it is not my province to discuss, but if, as without doubt is the case, the blocking of a minute artery in the brain will ultimately reduce a reasonable and self-restrained man to the condition of a vicious brute, it is obvious that morality and health are united to each other beyond the power of dissolution. If this is so, it must be further admitted that a man's health vitally influences his life, determines the quantity and quality of his work, the nature and variety of his temperament, the influence of his

Digitized by Google

intercourse with his fellows, and his general civic value. The conditions of civilised life often tend to increase the difficulties of maintenance of health. By crowding men into cities disease is more quickly propagated and harder to arrest. New varieties of disease are noticed; perhaps the variety is actually evolved. The changed environment of men tends to slowly bring about a corresponding change in their condition and vital necessities—a change always slow, frequently dangerous, and often ill-understood. Side by side may be noticed a group of moral and social facts, some of them highly disturbing and disintegrating to the previous social and conventional structures—facts which influence directly mental phases, which in their turn bring about much dislocation of healthy conditions and states. From this quarter arise all the fads, hobbies, and follies of experiment, which go far just now to interfere for the time being with true progress, and tend to substitute quack remedies for those social troubles which really have their roots deep down in the physical condition of men. It will be largely the duty of the medical man of the future to watch vigilantly these factors, observe their tendencies, and be on his guard in an attitude of expectancy for some manifestation of disorder which will test his sagacity while evoking his powers of admonition and advice. Among other things, it becomes his duty to enforce the claims and necessity for a duly organised department of public health. This is, perhaps, the one point upon which medical men may aspire to a reputation for disinterestedness. If, according to the common notion, we have such a direct selfish interest in disease that an epidemic or period of general sickness means prosperity for the medical man, it is clear that the whole duty of a medical man to himself should be to leave questions of public health alone, to treat with silence all agitation for the supply of pure water, the control of drainage and sewerage, for the improvement of hospital management, for the destruction of filthy and corrupt habitations, for the restraints on adulteration, on the sale of butcher's meat and fruit, for stricter administration of preventive laws with regard to quarantine, and generally agitation of any kind in the direction of health reforms. But what, as a matter of fact, is the case? It may be fearlessly asserted that Sir John Simon and Mr. Edwin Chadwick, both men eminent in our profession, "invented" Public Hygiene. These men undertook their work in pre-Pasteurian days, when all they could do was to improve paving and scavenging, attend to drainage, lighting, and water supply, and prevent overcrowding; but the gospel of cleanliness, at any rate, was established beyond all cavil.

In Great Britain, where there are, on the whole, fewer restraints on personal liberty than anywhere else in the world—where in consequence that education that free men give each other is of a higher standard than elsewhere; in Great Britain, I say, which stands at the head of the world in the matter of public health and all that pertains to it, matters have been brought to such a stage of perfection that our profession, backed by a highly trained and sympathetic public opinion, has practically more than once rolled the advance of cholera back from the shores of Britain. I was in England in 1892, when the cholera was raging in Hamburg, and nothing struck me more than the zeal and energy of our hygienists in teaching and warning the people of England what to do in the dread emergency. Millions of printed notices and bills were distributed by local health boards and health societies; sensible, pithy, and lucid little articles, useless, of course, except among an educated community, which, however, were so widely read and applied that, a'ded by them and a most watchful system of quarantine, Great Britain came through the threat of that scourge unscathed. Thousands of pounds were spent in that campaign, and never were thousands more profitably and perhaps more skilfully expended. The impulse to hygienic reform is weaker and more easily expended and exhausted in Australia and New Zealand than it is in Great Britain. There is nothing on this head even now to add to what was so well put before the Congress at its last meeting by Dr. Whittell in his presidential address on Public Health; but in our New Zealand towns generally, I believe, a movement in the right direction has commenced—public attention has been drawn to the matter by voluntary associations, which have now all the vigour of youth. I hope they will succeed in educating the people out of that ignorant impatience of control or still more deadly apathy which, both of them, are characteristic of weaker notions of the duties and obligations of civilised life. Legislation of a more central and less permissive character is desirable—legislation that does not depend for its administration upon the fortuitous and baffling currents of local political feeling. There is need also of increased activity among ourselves who, if we live *by* the public, live also *for* the public and have duties which, according to the trust reposed in us, are not measurable by fee or reward. It is always difficult to rise to higher lines of professional duty and activity, but for the younger men it is always desirable that they should cultivate aspirations and ideals; and of this I am certain, that in the immediate future there lies before our profession increased—vastly increased—scientific means and appliances for coping with our noble work and that to intelligently use these appliances and means will require increase of aptitude and development of opportunities for necessary training. For this augmentation of our power augments as well our responsibilities, it will demand on our part a greater mental energy, a more rigid discipline, a more single devotion to our ideal of duty, and a more general appreciation of the work submitted by a few eminent leaders to the opinion of thousands in the practice of our profession. Our increased resources should in the long run tend to produce among ourselves a distinct advance in professional type, while in society at large, by removing or obviating the causes and outbreaks of disease, they should increase the general volume of happiness and thus augment the social and moral well-being of mankind.

HOSPITAL ACCOMMODATION BY THE USE OF SHIPS (HOSPITAL SHIPS).

BY P. MURRAY BRAIDWOOD, M.D., F.R.C.S. EDIN.

Prelude. — That ever-recurring screen of ignorance euphemistically termed "experience" obscures at present the state of our Naval Medical Service. In the event of our nation being suddenly implicated in warfare how would the members of our oldest public service be cared for according to present arrangements? Our Naval Medical Service, as at present constituted, meets its claims fairly well, though those who form part of it have good reason to complain of its many defects. My aim in the following paper is to point out a better way of preparedness to meet emergencies. When this country is dragged into war we utilise our Naval Medical Service as it is, but have no reserved medical aid to requisition if necessary. Our Naval and Army Medical Services unite in supplying the needs of the sick and wounded. The navy during the Ashanti war undertook the lodging, victualling, and conveyance of the sick, and furnished everything necessary for these purposes; the army furnished medical and other attendance on the sick, provided all articles of hospital clothing and bedding, medical, surgical, and hospital appliances used by them, and undertook the washing of all hospital clothing and bedding.[1] Our standing army service can be supplemented by the "reserved forces" (militia, volunteers, &c.), with their medical officers; but in the case of our navy we can reckon on no such supplement. This lesson we have been taught by all recent wars and we continue still in the same state of backwardness. We rest contented with meeting our daily wants, and when our Government proclaims war we meet our suddenly incurred responsibility by makeshifts. We subsidise from passenger-carrying steamship companies large vessels like the *Carthage*, *Coromandel*, &c., at an enormous cost and have them knocked about (converted is the official phrase) to suit hospital purposes. This aim is, however, reached very imperfectly; such vessels are often, so to speak, "spongy," often unwieldy, with corners, crevices, and angles of all descriptions admirably calculated to house and retain objectionable peculiarities, and often needing repair. Henri Dunant exposed, in most pathetic language, the horrors of a battlefield when he described that of Solferino, where more than 300,000 men fought for fifteen hours on June 24th, 1859. Here "the best organised military medical services of three of the best armies of Europe were not able to render proper help and shelter to all the sufferers at the proper time." Rob. Hall in 1802 wrote in his "Reflections on War" that to confine our attention to the number of the slain would give us a "very inadequate idea of the ravages of the sword."

His detailed account of the accompaniments of warfare in his time is very touching and contrasts with those of the present day. The Red Cross Societies and like aids have remedied the sad state of matters which existed at the commencement of this century.

Historical sketch.—At different periods we read of some solitary instances of conventions made between the chiefs of belligerent armies for the neutralisation of the hospitals and the medical service of the sick and wounded received into the hospitals; but these contracts were mere temporary agreements depending on the momentary disposition of the chiefs in command of the belligerent powers and ended with the campaign for which they were made. "At the time of the Crusades Sultan Saladin allowed his enemies, the Hospital Knights of St. John, to remain nursing and tending their comrades in the city of Jerusalem, which he had conquered. In 1743, during the Austrian Succession War, an agreement was signed at Aschaffenburg between the Austro-Hanoverian (Pragmatic) army, under George II., represented by General Count de Stair, and the French army under Marshal de Noailles, the belligerents agreeing to regard the hospitals neutral and to give protection to the wounded. A similar convention was made in 1759 during the Seven Years' War, and signed by the English general, Sir Henry Seymour Conway, and the French chief, Marquis du Barrail. A convention between Louis XV. and Frederick the Great, stipulating the neutrality of the hospitals of the wounded and of all the persons belonging to the hospital service, was signed at Brandenburg, the 7th of September, 1759, by the French Marshal de Rougé and the Prussian General von Buddenbrock."[2] At the last naval battle between the Austrian and Italian fleets (1866) "the want of neutral aid, which was enjoyed by the warriors of the same nations on land, was bitterly felt by the navy." In impartial statistics it was stated that more than 400 men were drowned uselessly in this battle while they might have been easily saved.

My thoughts were directed to the deficiencies of our Naval Medical Service during warfare by the published accounts of the arrangements for the transit and treatment of our sick and wounded at sea during the Egyptian War in which we last took part, corroborated as these statements were by personal friends who served in this work on that occasion. With regard to hospital ships, I must, in the first place, call attention to a deficiency which exists in the organisation of the Naval Medical Service of most nations. This organisation is very expensive, and yet it seldom answers the purpose from want of a sufficient number of surgeons and nurses to supply the fleet and of the necessary room on board a fighting vessel for attending to the sick and wounded. The best medical help on board a war vessel might fail in time of action from want of space and proper security to exercise its functions. The treatment of the sick and wounded at sea is coeval with naval warfare, and its history divides itself into three periods. Thucydides (who died in 391 B.C.) and Herodotus (about B.C. 445) were probably the earliest historians of naval warfare. The former states that the engagement was one of man to man; the ships served only as the vehicles of this warlike force. Herodotus remarks that Duillius Nepos won the victory over the naval power of Carthage (B.C. 260) by grappling the enemy's ships to his own and boarding the Carthaginian ships with his legionaries, so that it became a man-with-man engagement. The second epoch of development in hostilities at sea began with the employment of artillery, which led to the destruction of the enemy's ship by shot. The third epoch commences with the introduction of steam, of iron-plated vessels, of rams, and of perfected cannon and shot. We are, however, interested in the medical aid obtainable during naval warfare.

Our first line of defence, our warships, is being supplemented, but no regard has yet been paid to affording necessary medical aid to those who may suffer when taking part in such defence. For some years past the Army Medical Department has received a considerable share of public attention and is ably aided by the promoters and members of the St. John Ambulance Association with its ever busy workers. The Naval Medical Department has no such adjuvant. This leads me to give a short notice of the "Red Cross" Societies, which afford the most noble example of the humanitarianism of this century. It is easy to fix the precise date of the origin of the Red Cross. This was the war in Italy in 1859. The "Hospitaller" orders were called into existence by the Crusades, and from time to time during certain wars the benevolence of private individuals induced them to found societies for succouring the sick and wounded. But no very deep traces of this spasmodic philanthropy remained, and the experience gained at various times was not available for subsequent generations. About 300 years ago a medical service attached to armies was regarded as a happy innovation and likely to be sufficient for every emergency, but this illusion was dearly paid for during the Crimean War (1853 to 1856). "Nevertheless, when the war in Lombardy broke out (1859) similar inefficiency was apparent, and cries of distress were again raised, which were emphasised by M. Henri Dunant's thrilling and heartrending description of the battlefield of Solferino. Hardly had three months elapsed after the publication of M. Henri Dunant's 'Souvenir de Solférino' before the suggestions it contained were discussed at a meeting of the Société Génevoise d'Utilité Publique." Feb. 9th, 1863, marks "the real starting-point of the Red Cross movement." A small committee of five members was appointed, but it was "not then known in Europe what prodigies had been accomplished in America by the Sanitary Commission of the United States during the War of Secession." To assist this committee in overcoming their early obstacles an International Conference was convoked and assembled in Geneva on Oct. 26th, 1863. Of Governments "Austria, Spain, France, Great Britain, the Netherlands, Prussia and six other German States, Sweden, and Switzerland took a direct part in this conference, whilst encouraging addresses were sent from Belgium, Denmark, Italy, Portugal, and some of the German principalities." In December, 1863, the first Red Cross Society was formed in Würtemberg by Dr. Hahn. From its first appearance the Red Cross has had many fervent apostles, of whom some belong to royal families. One of the most interesting points connected with the organisation of the Red Cross is the participation of women in the work. "That which is really international in the Red Cross Societies is the spirit which animates them, the sentiment of universal charity which forces them to hasten to any place where blood is flowing, and to feel equal sympathy for all the wounded whoever they may be," remarks G. Moynier.[3]

The hospital ship is to be regarded as an integral part of the fleet of war. It ought never to be wanting, and should accompany the fleet as the ambulance or the field hospital the army. As long as hospital ships and rafts are wanting the Naval Medical Service will be incomplete. Our work in warfare at sea consists not merely in tending the sick and wounded, but also in rescuing from an element whose strength it is above our power to control. The Red Cross Societies assist the Army Medical Service with men and material, and they should likewise supplement the Naval Medical Service. The aim of a Naval Ambulance Association such as I advocate must be to succour all during and after the battle, without regard to nationality, and to proceed with their rafts to the assistance of the crew. Directly after the battle they indicate by a signal that they are able and ready to receive the sick and wounded. The surgeons, nurses, helpers, and the *personnel* of these ships must be procured by the Aid Society through the local committee of the seaport where the hospital ship is to be fitted out, and placed under the direction of the chief surgeon of the fleet or squadron. It is necessary to establish a separate corps of surgeons, nurses, and helpers for the hospital ships' service at sea and to make them accustomed to the life on board ship. The peculiar nature of this field of work admits none inexperienced with life at sea without the risk of failure. Hence the importance of a naval ambulance association corresponding with the St. John Ambulance Association. Such *personnel* should be trained in times of peace; all that is regarded as requisite for the army is of no less consequence for the peculiar task at sea. It may be asked why not continue to meet our wants in the Naval Medical Service as we have hitherto done by hiring or renting from the large steamship companies some of their finest passenger steamers as required, and converting them into hospital ships? Two objections arise at once—such vessels are very costly in their conversion from one line of work into another, and they cannot be as efficient as a hospital ship arranged *ab initio* and built for the purpose. At the meeting of the Social Science Congress held in Birmingham during September, 1884, I first made public my views on hospital ships. At the meeting of the Hospitals Association in

February, 1885, Sir Edmund Hay Currie in the chair, I read a paper on this subject. My plans were exhibited and received awards at several international exhibitions. They form a portion of my more extensive scheme for a naval ambulance association for the treatment of sick and wounded at sea. The Naval Medical Service as at present constituted serves no doubt excellently in times of peace, but there is no reserve force to meet at once a sudden call or any system of efficient nursing in connexion with our mercantile marine. The organisation of a naval ambulance association would remedy these defects, and why should not our mercantile marine have the advantage of such a scheme? It is well known and generally acknowledged by hospital staffs that their patients recover better when treated in a house specially arranged and built for the purpose. This holds equally true of the treatment of sick and wounded at sea. A passenger steamer converted into a hospital ship can *never* be equally efficient with a vessel arranged and built for this special purpose.

Plans for hospital ships.—The accompanying illustration is made according to scale, and represents one of two forms of steamers—the spar deck and the shade deck. At the first glance at my plan it will be observed that the primary consideration has been to arrange for the comfort and efficient tending of patients at sea. To obtain this speed has been sacrificed and the propelling power (the engines) has been placed well aft. Each form of ship affords accommodation for 250 sick and wounded and carries sufficient stores to build and equip a temporary shore hospital. In the next place, special attention has been paid to the principle so much approved of in the construction of modern hospitals on shore, namely, economy of space, labour, and time. The patients being congregated instead of segregated in twos and fours can be properly nursed by a competent person in a room next door or near of call and a surgeon is at hand instead of being on another deck. My original designs represent vessels of two different types but of similar dimensions—namely, length 325 feet, breadth 50 feet, depth 25 feet, tonnage 3722, displacement about 4100 tons. By hospital ships are meant sea-going vessels propelled by steam and specially constructed and adapted for the treatment of the sick and wounded. Whilst very great advance has been made during recent years, especially since the Crimean campaign and the civil war in America, in the treatment of wounds and accidents among our shore population and in the proper conveyance of such wounded persons to hospital, very little attention has been given to the comfort of patients treated "on board ship." Brigade-Surgeon-Lieutenant-Colonel G. J. H. Evatt, M.D., says: "It is absolutely essential at the outbreak of a war to have a definite plan ready in the War Office for the equipment of this class of vessels, and that their staff of attendants and interior economy should be completely understood." The steamers I suggest would serve as: (*a*) ambulance ships of any size, but in motion; (*b*) isolation ships, at anchor or in motion, for infectious cases; (*c*) stationary ships anchored off unhealthy coasts; and (*d*) convalescent ships moored near large towns receiving patients from them and then going off for a longer or shorter cruise. When not needed for hospital purposes these steamers would make excellent transport ships.

An ambulance hospital organisation.—It is desirable to have an organisation at sea analogous to that so wonderfully perfected during recent years for the care of sick and wounded persons on land. A division of labour (a law of nature) permits of more work being accomplished well. If the tending of the sick and the feeding of the healthy be looked after by the same individuals neither receives the undivided attention it requires. When conducted on a large scale the nursing of the sick should be separated from the commissariat department. The proper and efficient treatment and nursing of sick and wounded persons "on board ship" necessitates the arrangement not only of an efficient naval *medical* service, but also that of an equally efficient naval *nursing* service. The medical care (by nurses as well as by medical men) of sick and wounded persons on board ship should be managed by an organisation entirely independent of extraneous influences, educated to its special work, and devoting its entire energies to such work. Next, as to the abodes in which this work is to be carried on. A certain and smaller portion of it can be conducted on shore, but much the larger part forms a continuous routine, which must take place on board ship. To do so special arrangements are required. Not only must the service which performs this work be "on the spot," but there must be ready at command the necessaries for the work. Not only must the medical and nursing staff to attend on the sick and wounded on board ship be in proximity to the patients, but they must have at hand the various apparatus and conveniences they may require in their work. In the drawings exhibited these ends are met. The steamer sketched is so arranged that the comfort of the patients is the primary consideration. To meet this the propelling power (the engines) is located out of the way, as near as possible to the stern of the vessel; a lift, worked by steam power and admitting of two patients being lowered together in their beds, carries the patients on board the hospital ship or lowers them to the deck on which they are to lie, the best and largest portion of the steamer is arranged as wards; on each deck not only is the nurses' room in immediate proximity to the ward, but there are also one or more surgeons' rooms, a dispensary, a ward kitchen, laundry, and other necessaries. As compared with the *Victor Emanuel* my hospital ships differ by being arranged for a number of patients to be treated in one compartment and watched over by a nurse or nurses who, from living next to this compartment or ward, have a constant oversight of its inmates. The officers (both those sick and those in health) are accommodated in the best part of the vessel—the stern. Many details, including such important matters as ventilation, heating, lighting of the various cabins and wards, are purposely not arranged for until a steamer is built on the plan shown. My wish is to see steamers of larger and of lighter draught built on the principles here enunciated, and after the general type represented, and utilised for the treatment of sick and wounded persons at sea.

Spar deck and shade deck ships.—Each to a certain degree has special merits that the other has not, and each may be made available or adapted according to the requirements of the special service for which it is used. A "shade deck" vessel has the special feature that it affords the best means of lighting and ventilating the lower wards through continuous skylights arranged along the outside of the walls. One of the disadvantages of this plan is that the space occupied by these skylights contracts the cubic space and makes the wards on the deck above of a smaller size than they would otherwise be. This sacrifice of space is avoided in the plan which accompanies this paper, somewhat to the detriment of the ventilation of the lower wards, for this has to be obtained by means of openings or windows in the vessel's side which must necessarily be closed in bad weather. The plan shows the "spar-deck" vessel, which gives much greater deck area than the former and larger wards in the main or upper deck. These wards occupy the full width of the vessel and, like those on the lower deck, are fitted with ventilating shafts passing through them to the lower wards. In considering the relative merits of these two classes of steamers, if built entirely for service as hospital ships, the preference should be given to the one which affords the most advantages. In each instance ample accommodation can be provided for all the accessories and necessary rooms for servants, dispensaries, linen and food stores, laundry, suitable kitchens, and all the requisites for a complete service of attendance which are usually provided in modern shore hospitals, and these can be arranged in immediate proximity to the several wards. Complete isolation can also be obtained, because of the vessels being subdivided by entire water-tight partitions or iron bulkheads extending to the upper deck. It might be well that these should not have any doorways through them, such as are usually fitted in similar water-tight partitions. In the plan, owing to the removal of the long skylights, the wards in the upper deck occupy the full width of the ship, and consequently are much larger and more commodious than those afforded by the other type of vessel. The uppermost wards of all (those in the long-deck houses) are exposed to the open air and are pretty much the same in both types, affording about the same accommodation in each instance. But these vessels can be employed for totally different purposes from that of hospital ships in time of war: they can be utilised for the carrying of infantry troops, and in such service as this the vessel with the largest available deck area would afford the most advantages. These are found in steamers of the type of the plan given, and this is therefore recommended as being the best model for a hospital ship, both on account of the additional facilities that such steamers afford through their more commodious accommodation

and on account of a larger deck area in the eventuality of the vessel being utilised for the carrying of troops. The steamer depicted in the plan is of light draught and would be able to ascend most rivers, so that if war were raging at a seaboard or near a large river or lake one of these steamers could sail up to a spot nearest the seat of battle and receive any sick and wounded, whilst it could also convey the necessaries for erecting on shore a hospital to accommodate 300 patients. Some may argue that on board ship sufficient air space is not afforded and cannot be obtained for the treatment during a long space of time of sick and wounded persons. This argument is based on a comparison with the space required in shore hospitals. But it must be borne in mind that a steamer being constantly in motion a speedier and more continuous circulation of air takes place than through a like amount of space on land. Our knowledge of such matters is as yet incomplete; but in my designs there is represented twice as much cubic area (floor space) for each patient as is afforded each saloon passenger in a first-class passenger steamer. We have no gauge by which to calculate how many cubic feet of air each patient in a hospital ship should have, but taking superficial area as our guide this result is obtained.

SOME CLINICAL REMARKS ON PNEUMONIA.[1]

BY J. EDWARD SQUIRE, M.D., M.R.C.P. LOND.,

PHYSICIAN, NORTH LONDON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

THE latter part of the present century has so advanced our knowledge of the influence of bacteria on most pathological processes that a study of their relation to the more important pulmonary diseases claims special attention. The various parts taken by micrococci and by certain distinct kinds of bacilli and how far they share in the initiatory and sequential phenomena of the differing forms of inflammation of the lung have to be considered. Not only has the germ theory of disease given increased interest to pathological investigation and to experimental research, but it has resulted in larger and clearer views of etiology and has important bearings upon clinical medicine both in prognosis and therapeutics. In the latter sense I do not here refer to the attempts at treatment by bactericidal drugs; this is now in the actively empiric stage, but it is one thing to kill bacteria in a test-tube and another to destroy them in the body. In the study of disease causation by the light of our knowledge of morbific organisms two factors demand attention—the seed and the soil; not only must the micro-organism be studied, but the conditions under which it will flourish. This is well recognised by the bacteriologist in preparing his culture media, and to the clinical observer and practical physician the influence of the soil on the life and virulence of the disease-germ are of the greatest importance. The "personal" equation in medicine has received a new interest and an increased importance from the discovery of the association of bacteria with certain diseases. The influence of the "personal equation" in disease is no new discovery, but we may note in the present day a greater tendency than was formerly the rule to treat individuals rather than diseases. In pneumonia the influence of the personal factor is well seen. Inflammation of the lung in a healthy child is a very different matter from the same accident occurring in an adult of impaired or shattered constitution, even though the initial lesion were of less extent or intensity. It is this individuality of each case of pneumonia which, whilst it renders the disease exceptionally interesting to the clinician, makes the management of each case a matter of peculiar anxiety. I propose to go through my case-book and touch upon some points of interest which my experience has furnished.

Etiology.—It is now almost universally agreed that acute lobar pneumonia must be considered as a general, not merely a local, disease. And although there are difficulties in the way of fully accepting this view there are many features of the illness which give it strong support. The discovery by Friedländer and Fraenkel of the micro-organisms with which their names are now associated seemed to furnish the proof of the general nature of the illness. We must, however, remember that similar or identical organisms are associated with other diseases besides pneumonia and are to be found in the saliva in health, and probably exist in the lungs and other organs without producing ill-effects. When some local change in the tissues furnishes a suitable soil these micro-organisms develop rapidly and produce inflammation, whilst the toxic substances formed by them give rise to general symptoms. These local changes may be caused in various ways—for example, by traumatism or by chill—and they are more readily induced in organs of lowered vitality, whether this is permanent or temporary. Thus we find alcoholism predisposes to pneumonia, and that inflammation of the lung is a common accident in many illnesses where the general vitality of the tissues is impaired—e.g., typhoid fever and influenza. So, too, the fatigue consequent upon excessive exertion renders a chill more dangerous; the overdone competitor in a long distance bicycle ride finishing in a cold drizzle is more likely to get pneumonia than the spectator who has stood shivering to watch the result. It is a fact, sometimes imperfectly recognised, that over-fatigue is an important factor in the production of pneumonia. I have seen more than one case of pneumonia following a chill during the latter part of a long bicycle ride. The changes in the lung tissue which favour inflammation are probably the result of nerve influence which may originate at a distance from the affected organ. We know that in animals inflammation in the lung will result from injury to the vagus. The influence of chill to the surface of the body probably affects the lung by reflex nerve action. Such a result is perhaps most likely to ensue with exhausted nerve control, and pneumonia from chill is thus more prone to happen during fatigue. The pneumonia of alcoholism has been considered to be a trophic neurosis originating at the vagus centres, and possibly the poisons of enteric fever and influenza may act in a similar manner. On the other hand, the lung tissue may be directly damaged by local irritation. This may be mechanical, as from a blow, fractured ribs, or inhaled mineral particles, or the local irritation may in some cases be due to the toxic effects of micro-organisms. It may be that even local irritation produces its effects by reflex nerve action. These considerations may help us to understand the occurrence of pneumonia under such widely different conditions as traumatism and chill, or as a secondary result of disease.

Just as fatigue increases the risk from chill, so may the debility after an illness render a chill more dangerous. In the following case we have a good example of the effect of

[1] A paper read before the Harveian Society on Feb. 20th, 1896.

Digitized by Google

measles in predisposing to pneumonia from chill. A man aged about thirty-five years had an attack of measles, which went through its course without any noteworthy characters until the patient was sufficiently well to sit up in his bedroom for an hour or two during the day. Being so well he sent the nurse out for a walk and in her absence he took a bath, and then, without completely dressing, he threw open his window, although it was in March, and began to arrange some papers. That evening he had a rigor, and the temperature, which had been normal for some days, ran up. He had a sharp attack of pneumonia. The readiness with which convalescents from measles suffer—and often suffer severely—from chill, though well known to medical men, is imperfectly appreciated by others, and the large mortality after measles is due to the preventible complications and sequelæ. The case I have just mentioned is one of idiopathic pneumonia following after measles and is quite different from the pneumonia which occurs in measles as a part of the disease, coming on before the original fever has disappeared. The lungs are always affected to some extent in measles (as a part of the disease) and are liable to remain for a time in a condition which renders them a suitable soil for the development of any micro-organisms which may be present in these organs already or which may get to them from outside. Thus we find measles often an antecedent to pulmonary tuberculosis.

I have seen several cases of pneumonia associated with enteric fever and some of them have had this point of special interest—Was the pneumonia present the substantive disease and the actual cause of the illness or a complication not infrequent of enteric fever? The recognition of the signs of pneumonia has, in some cases which I have seen, been taken to explain the illness and so misled as to the true nature of the case. Whenever in obscure cases signs of pneumonia are detected it is important to consider whether the condition of the lung will sufficiently explain the course of the illness as well as the existing symptoms. As a good instance of the importance of this I may refer to a case I saw recently in consultation. I was asked to see a boy aged about eleven or twelve years because pneumonia had been diagnosed. On examination there was no doubt as to the presence of pneumonic patches in both lungs, especially the right, but the lung trouble did not seem to me sufficiently intense to explain the serious condition in which the boy obviously was at that time. Further examination disclosed pericarditis with effusion. Pericarditis may complicate pneumonia, but here on further inquiry I was led to a diagnosis of acute rheumatism, which the further course of the illness seemed to justify. The boy recovered, but with an endocardial murmur, which has now, after three months, almost disappeared.

The pneumonia of influenza presents some peculiar characteristics. The sputa may be rusty and the symptoms severe, but the physical signs are often obscure and the course of the disease unexpected. One marked peculiarity which I have noted is the tendency of the pneumonia to appear in some distant part of the lung or on the opposite side when resolving at the original seat. Here is a characteristic case. A young man about twenty-five years of age was seen in consultation in the country. On the right side of the chest the percussion note was "tubular" (high-pitched and sharp, with diminished resonance, but not dull) from the apex to the fourth rib, with tubular breathing. The rest of the right front was clear except for a few crepitations. The right back was dull almost all over. The left side was clear. Expectoration was very tenacious and had a slight brick-red colour, not typically pneumonic. The medical history showed that the pneumonia commenced at the right base, and as that resolved the apex became affected with another rise of temperature. This is quite different from what is found in typical acute pneumonia.

With reference to the influence of malaria on pneumonia, in my experience at Suakin in 1885 malaria was not a frequent cause of illness, except in those cases which have been called "typho-malarial," and which I believe to be dependent upon malarial poisoning. In these cases, as well as in some of the cases of enteric fever there, pneumonia occurred as a complication. A malarial pneumonia has been described, but Osler, with his large experience of malaria, says he has never yet met with a case of pneumonia which seemed to be in any way connected with paludism. The debility which is induced by a malarial attack may, however, predispose to pneumonia, as in the following case. A man aged thirty-three years arrived in England in April from the West Indies, where he had been for about five months, and had been eight weeks seriously ill with malarial fever. I saw him in consultation the day after he landed and found pneumonia affecting the right apex. When I saw him again, three weeks later, the chest was clear, the pneumonia having completely resolved. Tubercle had been suspected as the cause of the lung mischief, but no bacilli were found in the sputa, and the complete resolution within three weeks is in itself almost sufficient to confirm my opinion that the pneumonia was not due to tuberculosis. The patient recovered and still keeps well after nearly three years. Whether malarial fever predisposes to pneumonia or not, the cachexia left after severe malarial poisoning adds to the danger of a subsequent pneumonia. Some years ago I attended a man aged thirty-nine years during an acute attack of pneumonia, from which he died on the tenth day. The patient had served in the marines and had suffered from malaria. The illness with the pneumonic attack was very acute, the temperature was high, with delirium from the fifth day. In this case I believe the previous malarial poisoning had left him without power to resist any severe illness, for his age and habits were not unfavourable to recovery.

The foregoing remarks will emphasise the importance of the "soil," in addition to the causative bacteria, as a factor in pneumonia. There is this analogy between pneumonia and tuberculosis: in both a micro-organism is the essential cause, but the germ is harmless unless the soil is favourable to its development. The difference between the two diseases depends upon the different characteristics of the causative micro-organisms. The pneumococcus or pneumo-bacillus, developing rapidly, quickly produces its full effects, and sufficient toxines are formed to cause an acute illness and usually to poison the germs before they can become widely distributed. Thus we have a sharp but short illness usually terminating by crisis. The tubercle bacillus also produces a pneumonia, but develops slowly; the consequent small total output of toxines in the early disease leaves the blood-stream non-poisonous to the bacilli, and they are carried by it to other parts, where they set up fresh centres of disease. In pneumonia, as in tuberculosis, the various predisposing causes, such as cold, exhaustion, or debility, render the individual susceptible; the character of the "tissue soil" (to quote Osler[2]) has been so changed that the specific germ of either can grow and produce its ultimate effects.

Course and symptoms of pneumonia.—There is a very interesting point on which opinions are not unanimous—namely, whether there are cases which justify a diagnosis of acute congestion of the lung. The French consider active congestion of the lung to be a distinct disease (maladie de Woillez), but most authorities in this country consider the cases so described to be cases of pneumonia. Cases undoubtedly do occur, commencing suddenly with the symptoms which mark an attack of pneumonia, which either terminate fatally before the lungs become consolidated or which resolve without going through the ordinary course of pneumonia. Such cases may be termed "abortive pneumonia," and these are the cases to which the term "acute congestion of the lung" is sometimes applied. I select two of my cases bearing upon this point—one in a child, the other in an adult. A little girl aged four and a half years, who was said to have had congestion of the *left* lung the previous winter, was taken ill rather suddenly with feverish symptoms and slight cough. I found the temperature considerably raised and the base of the *right* lung dull. A mustard poultice was applied, and the next day the dulness had cleared and the temperature went down in two days. In the other case a woman past middle age, having just got over an illness of a few days' duration (supposed to be influenza), was found to have a return of fever with signs suggestive of pneumonia. When I saw her the next day the temperature was 101° F., and there was diminished resonance over the right base up to the angle of the scapula, with weakened breath sounds and fine crackling over the affected area. A mustard leaf was applied. I again saw her three days later. The temperature was down and the patient felt well. The right base was resonant, the breath sounds still somewhat weaker than on the left, but there were no crepitations. This was hardly a hypostatic congestion, for it was accompanied with a rise in temperature and the conditions which induce hypostatic congestion were absent. These two cases, though presenting different clinical phenomena, have this important characteristic in common—viz.,

[2] The Principles and Practice of Medicine, second edition, p. 547.

Digitized by Google

that in both the febrile illness was short and the consolidation of the lung was rapidly absorbed, whereas the consolidation of pneumonia usually takes some time to resolve after the febrile illness is over. In this sense they may both be described as "abortive" pneumonia.

The pathological conditions found in pneumonia may be referred to in explanation of such cases. These, as given by Dr. Douglas Powell, consist "first of an acute hyperæmia of the affected lung resulting in a fibrino-corpuscular exudation into the alveoli, sometimes including the smaller bronchioles and forming a film upon the pleural surface. This exudation, secondly, coagulating *in situ*, fixes the lung in a state of immovable expansion more densely solidified than it could be by any artificial injection with coagulable fluid."[3] The facility with which these exudations may be absorbed varies with the nature of the effusion and of the corpuscular elements and the degree of coagulation obtained. In the cases of which I have just been speaking the fluid exudation is presumably absorbed before coagulation takes place. We have thus only the first stage of the pneumonic process.

It is unnecessary here to describe the symptoms and course of an ordinary case of pneumonia, but I propose to mention one or two peculiarities or divergencies from the normal course which have come under my notice. We sometimes find that in cases of acute pneumonia the fever subsides gradually instead of by crisis, and it has seemed to me that this is more common in hospital practice than in cases seen at home. Possibly removal of the patient may have something to do with this. If a patient is taken to hospital when the disease is well established—say from the third day onwards—the febrile period becomes somewhat prolonged and the crisis is delayed or wanting. When consolidation of the lung has occurred resolution necessarily takes time, and in the most favourable cases is not complete until some days after the temperature has fallen. We meet with cases, however, in which this resolution is delayed for a considerable period, it may be several weeks or even months. I have notes of a case of a girl aged twelve years in whom resolution was not complete for nearly two months, but it may be delayed longer than this. Such cases may get absolutely well, as this girl did, the lung eventually clearing up completely. In other cases where resolution is delayed we find some further mischief, either as the cause or a result of the delay; for example, tubercle or pleuritic effusion or an abscess may form in the lung. I have in a previous paper[4] before the Harveian Society drawn attention to the risk of tuberculosis after pneumonia, especially in those cases where resolution has been long delayed. The pneumonic process nearly always leaves the lung in a condition favourable to the growth of germs which may subsequently reach the organ; thus we find that, unlike what is the rule in a general disease, one attack renders the person more liable to suffer again from pneumonia and predisposes also to phthisis. Some years ago I had a case of gangrene of the lung following pneumonia,[5] and I have lately had an interesting case of pneumonia affecting the upper lobe of the left lung in which a pyo-thorax developed which was also localised in the upper portion of the left chest. The patient, a boy ten years of age, was one of three inmates of a school who developed pneumonia. In due course the crisis occurred in all, but whereas two of the boys had an uninterrupted convalescence the temperature of the third, after being down for a day or two, ran up again and showed the large diurnal range of septic fever. The left chest was immovable in respiration and quite dull on percussion. The boy had a tuberculous family history, and I took him into hospital to have him under observation. Being satisfied of the presence of fluid in the pleural cavity I got Mr. Watson Cheyne to open the chest. A large quantity of offensive pus was evacuated and the boy made a good recovery. I have had several cases of empyema following pneumonia, but this case of empyema localised at the apex is exceptional.

The case just quoted leads one on to refer to cases of apex pneumonia. Pneumonia affecting the apex of the lung is not necessarily more severe or more dangerous than inflammation occurring at the base. Cases of apex pneumonia are sufficiently common to make it unnecessary for me to quote instances here. One important point of interest in these cases is the difficulty of distinguishing between a simple pneumonia in this situation and tuberculosis. The apex of the lung being the most frequent seat of commencing tuberculosis we may be led to diagnose phthisis when we get consolidation of the apex without fully considering the history and physical signs. It is important also to remember that pneumonia may be induced by a patch of tubercle, the presence of which is not recognisable until the surrounding pneumonia subsides. I have elsewhere referred to cases illustrating this and other points in reference to the connexion between pneumonia and tuberculosis.[6]

With regard to the sputum in pneumonia, viscidity is perhaps a more general characteristic than the rusty colour. In catarrhal pneumonia the rusty colour is not infrequently absent, and it may be so in lobar pneumonia. On the other hand, I have seen the characteristic rusty sputum when careful examination failed to detect any dulness; here the pneumonic patch was probably deep-seated. The prune-juice expectoration, which is often a sign of danger, is not always so. The change from marked viscidity to a more liquid as well as darker sputum is more significant of danger than the deepened colour alone.

Diagnosis.—Theoretically the signs of pneumonia are sufficiently characteristic to be recognised easily and with certainty, but practically we find ourselves often obliged to weigh carefully all the evidences obtainable before we can give an opinion. I have mentioned the difficulty occasionally met with in deciding between tuberculosis and pneumonia, and I have on more than one occasion found a pleural effusion where pneumonia has been diagnosed. Pleurisy may follow pneumonia, and when the signs of pneumonia have been correctly recognised in the first place dulness on percussion at subsequent examination has been interpreted as indicating non-resolution when it was in reality caused by fluid. Careful auscultation should be practised throughout the course of a case to avoid such an error, and repeated testing of the vocal fremitus must not be omitted; but even with this care the mistake is not always avoidable. The dulness of hypostatic congestion or of œdema from heart or kidney disease and the dry crackle of emphysema may at first suggest the presence of pneumonia. But with the aid of the thermometer and consideration of the history and general symptoms there should be no difficulty in forming a correct opinion. The marked alteration in the pulse-respiration ratio—due to the quickening of the breathing out of proportion to the acceleration of the pulse till we may have one breath to every two pulsations instead of one to four—may often guide us to the detection of even a limited pneumonia. Finally, we have to remember the possibility that the pneumonia may be symptomatic of some disease—such as typhoid fever—requiring the fullest attention, or an accident of a tuberculosis which would modify prognosis.

Treatment.—I strongly advocate the stimulant treatment of pneumonia. We have here an illness which is of short duration but often of great severity, and recovery is almost certain if we can keep up the patient's strength till the fever is past. As most of us know by experience, exhaustion may come on so rapidly that if we wait until it shows itself treatment may be too late to counteract it. We may, however, do much to prevent this excessive exhaustion by commencing with stimulant treatment from the first. By stimulant treatment I do not mean necessarily or solely alcoholic treatment, though I consider alcohol one of our most important drugs in the treatment of pneumonia. A full supply of nourishment in suitable form is necessary as well as stimulant drugs, and good nursing is essential. In many cases the nurse is what the practitioner makes her; and if the medical man shows a knowledge of what good nursing means and gives minute instructions to the nurse, taking measures also to satisfy himself that his instructions are carried out, he will probably have little cause to complain of want of attention on the nurse's part. In severe cases I am in the habit of writing out a time-table for the nurse, stating not only the hour at which nourishment, stimulant, or medicine shall be given, but the nature and quantity of each to be administered on each occasion. I then expect the nurse to keep a diary which I may compare with my time-table at every visit. Whether it is ever allowable to cease giving a patient food, drink, or medicine on the grounds that it can do no good and only bothers the dying patient we need not now discuss. It is certainly never justifiable in a case of pneumonia. I can recall two

or three instances of recovery after a patient had been "given up" in which any relaxation of the details of nursing would have taken away the last hope. I cannot too strongly insist on this point.

Local applications over the affected portion of the lung are, in my opinion, very useful. Whether they exert any appreciable influence on the disease may be questioned, but they often ease the patient's discomfort and soothe him. I prefer a poultice as generally most comfortable to the patient, but ice-bags are also recommended. The inhalation of oxygen is often of service, especially when a large extent of lung is consolidated; and I have seen marked improvement in breathing and in general symptoms from placing a patient with high fever in a tepid bath, after which the patient dropped off into a quiet sleep. As to drugs, there is room for individual choice within a certain range, and symptoms will guide us in our selection. I have a liking for carbonate of ammonia, to which digitalis or strophanthus may be added if there is any danger of cardiac failure. A caution is to be observed as to the use of even simple aperients. Of course the patient must not be allowed to get up, and sudden danger may result from undue action of the bowels. An enema may be needed, and this means of giving both nutriment and alcoholic stimulant also must not be overlooked.

With regard to alcohol, I prefer to begin to use it early in small doses (two to four ounces in the twenty-four hours), and to increase the quantity on the first indication of increasing weakness. Many cases will complete their course without needing any increase of the initial amount, but I have known cases where the alcohol has had to be given in large amount for a day or two. I sometimes tell the nurse in serious cases that if exhaustion is great an extra half ounce of brandy should be given before calling the medical attendant. I well remember, when I was a house physician, a patient with double pneumonia who took about thirty ounces of brandy in one twenty-four hour period. The case was pronounced hopeless by the visiting physician, but I and the nurse decided that we would keep the patient alive over the crisis if it could be done by stimulant, and we succeeded. This experience coming so early in my medical career made a great impression on my mind. I believe there is no better stimulant for use in the exhaustion of pneumonia than alcohol; others I know prefer not to use alcohol at all, but if they are wise they make use of some other stimulant in such cases as the one to which I have just alluded. As I have already intimated, your pneumonic patient will probably recover if you can keep him alive over the tenth day. The personal equation has such a marked influence on the character of the disease that, though we may lay down some general principles for the treatment of pneumonia we must be guided as to details by the individual peculiarities in each case.

Harley-street, W.

THE PROVISION OF ISOLATION HOSPITALS: A REPORT PRESENTED TO THE ESSEX COUNTY COUNCIL.

By J. C. THRESH, M.B., CH.B. VICT., D.SC. LOND., D.P.H. CAMB.,

MEDICAL OFFICER TO THE ESSEX COUNTY COUNCIL, ETC.

In the various districts which I have visited I have found that many members of the sanitary authorities hold very erroneous views on two important points—viz., the objects for which isolation hospitals are required and the character of the accommodation necessary. It will probably be well, therefore, if I briefly refer to both these subjects.

The most erroneous opinion held is that isolation hospitals are structures only required for use during the prevalence of an epidemic of some of the more serious infectious diseases, such as cholera, typhoid fever, small-pox, diphtheria, and possibly scarlet fever. It is quite true that these are the diseases most frequently isolated in hospitals of this character, but it is a fundamental error to suppose that they are only to be used when an extensive epidemic prevails. Their real use, their greatest use, is for isolating the odd cases of infectious disease which occur in all districts, cases which may have been imported from without or the origin of which cannot be certainly traced, but cases which if not promptly removed become foci from which epidemics start. If the important fact be once clearly grasped that isolation hospitals are intended to prevent rather than to arrest epidemics much misconception on certain other points will be prevented.

The second error to which I refer relates to the nature of the accommodation required and really arises out of the first. I have frequently heard it stated that as the hospital would only be occasionally used a permanent structure is not needed, that a wooden hut or tent which can be put up at one or two days' notice is all that is necessary to meet any emergency. On the other hand, the view is sometimes expressed that a permanent structure ought to be erected of such a size that it would afford accommodation for all the cases arising in a widespread epidemic. As usual, the truth lies between these extremes. Temporary structures such as those referred to are totally inadequate, whilst permanent hospitals capable of receiving all the patients in a widespread epidemic are totally unnecessary. Temporary hospitals are of little value for several reasons. 1. They are rarely erected until an epidemic rages and therefore do not fulfil the primary object of an isolation hospital. 2. They are never in actual readiness. Valuable time is lost in erecting the structure or in preparing it for occupation, obtaining nurses, &c. 3. When erected they are neither so commodious nor comfortable as properly equipped permanent hospitals. That such hospitals have, though very rarely, their uses will be seen shortly. A permanent hospital capable of receiving all the cases which may occur during an epidemic period is unnecessary because with a small permanent hospital and a proper administrative block the earliest cases notified can be isolated and epidemics will be of infrequent occurrence; in fact, small hospitals properly utilised would probably prevent nine-tenths or more of the epidemics which now occur. If notwithstanding early isolation an epidemic happens then temporary accommodation can be provided within the hospital grounds to meet the exceptional emergency. The only legitimate use for tents and wooden structures is to supplement the permanent buildings on those very rare occasions when they are inadequate for the requirements of the exceptional conditions.

There is a further question with reference to isolation hospitals well worthy of consideration, and that is whether it is better to have a few large hospitals throughout the county or a larger number of small ones. This question can be discussed from two points of view—efficiency and economy. I will not take up space by discussing this subject, but will simply state the conclusion I have myself arrived at after full consideration. I think that only under exceptional conditions is it advisable to have an isolation hospital serving more than one Poor-law union. Such an area usually includes one or more urban districts surrounded by a rural district. Where a town—i.e., an urban district—is surrounded by a rural district within the same union it will in probably all cases be desirable to have a hospital for their joint use. Such an arrangement will be of advantage both with regard to efficiency and economy, economy in first cost and economy in management. The number of beds necessary will vary in nearly every district, chiefly depending upon the degree to which the population is crowded on space and the extent to which overcrowding in cottages prevails. In thinly populated rural districts some considerable proportion of the cases of infectious disease which occur will not require removal; in the poorer quarters of towns and in populous villages nearly every case may have to be removed. Again, in the manufacturing towns, where there is a large proportion of children, more accommodation will be required than in agricultural towns, where there are fewer children. Speaking roughly and having regard to the special requirements of the county, in the urban districts the permanent provision should be one bed for every 1000 to 1500 of the population, and in the rural districts one bed for 2000 to 3000 of the population. In laying out the hospital grounds provision should be made for the erection of temporary structures should such ever be required to supplement the permanent accommodation.

There is one disease which has exceptional features and requires exceptional treatment. I refer to small-pox. The prevalence of no disease, excepting possibly cholera, causes greater alarm or more easily creates a panic, and yet it is one of the most controllable, if not the most easily controlled, infectious disease with which we in this country have to deal. Promptly isolate the sufferers and revaccinate all

Digitized by Google

persons who have to come near them and the disease will be effectually and at once stamped out. Unfortunately the infection of small-pox can be aerially conveyed to some considerable distance, but I am firmly convinced that this only occurs where a considerable number of patients are aggregated in one hospital. I do not think it would ever occur in our smaller hospitals, especially if the patients were treated in Berthon huts or properly constructed hospital tents.

It is of course desirable that provision should be made for treatment of two diseases, scarlet fever and diphtheria for instance, and for the separation of the sexes. For these purposes four wards will be required. As examples of hospitals which meet all the Local Government Board requirements the following may be cited:—Chelmsford Rural District: Hospital with two wards (five beds) and nurses' room, and caretaker's house with four bedrooms, two of which are used for isolation purposes. The cost of the buildings was £1000, of the disinfector and ambulance £100, and of sheds for same £100. Saffron Walden Urban and Rural Joint Hospital: Caretaker's house, hospital with two wards (four beds) and nurse's room, drainage, outbuildings, &c., cost £1200. The old hospital (a small farmhouse) adjoins the new premises and is used when more than one infectious disease is prevalent. Southend Urban District: The hospital here, which is approaching completion, has two ward blocks each accommodating about ten patients, administrative block, laundry, mortuary, disinfecting apparatus, &c. The estimated cost is for buildings £3700 and for furnishing £350. Three different diseases can be isolated and the sexes separated. Halstead Urban District: The hospital here is also approaching completion and resembles the one in the Chelmsford rural district. The administrative block is, however, larger and the whole more expensively built.

Other subjects, such as the equipment of hospitals, provision of ambulances, disinfecting apparatus, hospital management, &c., which require consideration, I shall report upon at an early date.

Chelmsford.

A CASE OF CARCINOMA OF THE UTERUS COMPLICATED BY PREGNANCY.

BY R. M. LEITH, M.B., C.M. EDIN.,

LATE ASSISTANT DEMONSTRATOR OF PATHOLOGY, EDINBURGH SCHOOL OF MEDICINE.

THE following case presents several points of sufficient interest and rarity to warrant its publication.

A woman aged twenty-nine years, five months after her second confinement, was sent to Dr. Ramsay Smith on Feb. 28th, 1896, for gynæcological examination and opinion. The result of the examination is embodied in the following note: "Cervix uteri split in several directions and eroded; what remains of it is hard, nodular, and immovable, and covered with cauliflower excrescences; os patulous and its margins friable, the whole bleeding freely on touch. Possibly malignant disease and a case for hospital." The patient, however, refused to go to hospital, so she was received into Dr. Ramsay Smith's private Home on March 9th, where she came under my observation. Her condition on admission was as follows. In appearance she was a small spare woman, much emaciated, with flushed cheeks and poor appetite, but with no cachexia. She complained of severe gnawing pain over the sacral and lower lumbar regions, the pain sometimes shooting down the outside of the thighs. The pain was so constant as to render her almost helpless. According to her own statement the patient had been five years married. Her first labour, eighteen months ago, was lingering, and the child was stillborn. Her second confinement, five months ago, extended over a period of five days. The child (stillborn) was rather large. After the confinement she complained of pain, and as her medical attendant put off examining her she consulted another medical man, who sent her on to Dr. Ramsay Smith, as stated above. The nature of the condition as determined by the first examination was doubtful. In favour of malignant disease were the rapid emaciation, pain, hardness and immobility of the cervix, and infiltration of the vaginal vault. Against this were the comparative youth of the patient, the absence of menstruation and hæmorrhage, except at the examination described above, the absence of rectal and vesical symptoms, and the recent pregnancy, which was only the second. Metastasis and cachexia were both absent, but these conditions occur so seldom in cancer of the uterus that nothing could be argued from their absence. The family history was decidedly good, tuberculosis and cancer being absent from the record. Though the diagnosis was doubtful the indications for treatment were clear enough. If the condition was non-malignant then the proper treatment was to remove the excrescences and stitch the rents in the cervix. If the condition should turn out to be malignant then the only possible course, considering the nature of the case, was to remove as much as possible of the diseased tissue as a palliative measure. So, without further examination, Dr. Ramsay Smith operated the day after her admission. After a preliminary hypodermic injection of morphia and atropia the patient was chloroformed. All the diseased tissue was rapidly removed by help of the finger-nails and curette, leaving the uterus excavated in all directions. There was a good deal of bleeding and the smell of the tissue removed was most offensive. Altogether about four-fifths of the entire uterus were removed, and the cavity, after being swabbed thoroughly with iodised phenol, was packed with iodoform gauze. The after-treatment consisted of hot douches three times a day with permanganate of potassium and mild morphia suppositories. In a week the patient was able to be up, was comparatively free from pain, had become more cheerful, and was acquiring an appetite for food. Microscopic examination confirmed the diagnosis as determined at the operation—cancer. Some facts elicited subsequently make the history of the case more complete and interesting. Pain and slight bleeding had usually occurred on connexion before the last pregnancy, and this, with other circumstances, point to the great probability, if not certainty, that pregnancy had occurred after the uterus had become diseased. The first labour, eighteen months ago, had been tedious, and the child was stillborn, leading to the presumption that cancer had originated in a torn cervix after the confinement. In cases of cancer of the uterus inquiry as to the condition of the husband's penis often elicits the fact that smegma accumulates behind the glans and under the prepuce, and this was so in the present instance. The outstanding points of interest in this case are that pregnancy occurred in a young woman in a cancerous uterus and went on to term, the disease being unsuspected, and that the symptoms were so obscure and indefinite even when the disease had become so extensive as to render a radical operation hopeless. The lesson to be learned is that every patient who has a tedious labour should be examined some time after confinement, and that, though it is not necessary to operate on every case of torn cervix, it is desirable to operate on some.

Rhyl, North Wales.

HUNTERIAN SOCIETY.—A clinical meeting of this society was held at the London Institution on March 25th, the President being in the chair. Sir Hugh Beevor showed for Dr. Woods a case of Spasmodic Tremor in the right hand and forearm which had been treated by short hypnotic sleeps for about six weeks. Gradual recovery took place. He also showed another case of a man aged forty-three years who was successfully treated by the same means for localised headache and giddiness.—Dr. F. J. Smith showed a man the subject of Addison's disease treated by supra-renal extract twice daily. The pulse had improved and the vomiting was less.—Dr. Arthur Davies brought before the society a case of imperfect closure of the left upper eyelid in a patient who suffered from mitral regurgitation. Suggestions as to the cause of the imperfect closure of the eye were made by the President, Dr. F. J. Smith, Sir Hugh Beevor, Mr. Rawes, and Mr. Tubby.—Dr. Davies finally expressed his opinion that the cause of the apparent projection of the eye was spasm of the left orbitalis muscle.—Dr. Arnold Chaplin presented the case of a man aged forty-six years the subject of bronchiectasis of the lower lobe of the left lung. He was placed in a room eight feet in each of its dimensions and subjected to the vapour of creosote for from a half to one hour daily. After some weeks the following results were noticed. The temperature fell to normal, the fœtor of the breath was less, there was a decrease in the moist sounds of the chest, and the patient had gained 5 lb. in weight.—Sir Hugh Beevor, Dr. Davies, Dr. F. J. Smith, and Mr. Tubby joined in the discussion which followed, and Dr. Chaplin replied.—Dr. Glover Lyon showed a patient the subject of Extensive, Painful, Glandular Growths, probably due to lymphadenoma.—Dr. Davies inquired if bone marrow had been given.—In his reply Dr. Lyon stated that there was no anæmia present.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CASE OF SEVERE HEAT-STROKE; RECOVERY.

BY P. J. ATKEY, M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON TO THE PENINSULAR AND ORIENTAL STEAM NAVIGATION COMPANY.

As cases in which the temperature has risen over 108° F. and the patient has subsequently recovered are not often recorded, or at any rate well authenticated, I think the following will be of interest.

The patient, aged twenty years, of good physique, was a steward on board the Peninsular and Oriental steamship *Parramatta* and on his first voyage from England. He was quite well until the Red Sea was reached, where the heat became very trying and oppressive, although the temperature of the air in the shade did not exceed 90° F. He first came to me on July 21st, at 12 A.M., complaining of severe pains all over, but worst in the back, and of great weakness in the limbs. His temperature was then 102·5°, the skin was dry, and the pulse full and rapid. I gave him ten grains of phenacetin and sent him to lie down. He stated that he had not been directly in the sun and that except for feeling tired, which he put down to extra work, had felt quite well till half an hour previously. At 2 P.M. I was sent for, as he seemed much worse, and found him in his berth quite unconscious; his breathing was fast and shallow and the pulse was full and laboured. While making arrangements for moving him I took his temperature in the axilla and found it to be 108·2°. His eyes were wide open and staring, the pupils being slightly contracted and not acting to light. He was immediately put into a bath of iced water and at the same time ice was applied to the head. When put into the bath his respirations became deeper, though still fast, and his pulse quieter. After five minutes his temperature had fallen to 103·5°, and after being in eight minutes, his pulse getting bad, he was put in a blanket on a bed and a little brandy poured down his throat. His pulse was now 108, the temperature 103°, and the respirations quick and weak. A few minutes later he began to vomit and brought up a large amount of semi-digested food, after which the pulse and respiration both began to improve, and at 3 P.M.—i.e., one hour after I first saw him—his temperature was 102° and the pulse was 96. He continued like this till 8 P.M. with teeth firmly clenched, and he could not be made to take any fluid, being still quite unconscious, when he suddenly raised himself in bed and began to struggle, and soon afterwards swallowed a little milk. His temperature had since 4 o'clock kept between 100° and 100·8°. I now had him fed with a little milk occasionally and gave him seven grains of calomel. He continued quiet, apparently sleeping, with the pulse about 100 and the temperature from 99° to 100° till 3 A.M., when he regained consciousness and talked sensibly, recognising people. The calomel acted freely three times later in the morning, and during the day (July 22nd) his temperature varied between 99·2° and 99·8°, the pulse ranging between 80 and 84. On the 23rd his temperature was between 98·2° and 99·8° and the pulse between 80 and 90. On the 24th and 25th the maximum temperature was 98·8°. The patient had been doing well and complained of nothing except at times a slight frontal headache. He took his diet well, which consisted of slops. On the 27th the patient was up on deck for an hour and complained only of weakness. On Aug. 1st he returned to his ordinary duties and seemed quite well.

Having had a considerable number of cases of insolation under my care since I have been in the service of the Peninsular and Oriental Company I can say that they do exceedingly well on board ship, and as there is an unlimited supply of ice and every necessary immediately at hand have a better chance than they would have elsewhere. The rapid recovery and absence of sequelæ, so common after severe heat-stroke, are the most interesting points about the above case, and I should like to know what other similar cases have been recorded. Dr. Clennell Fenwick of St. Thomas's Hospital, and Mr. Gilmour, R.N., very kindly gave me every assistance, and were both present when the temperatures were taken.

Sydney, N.S.W.

A CARDIAC CURIOSITY.

BY J. REGINALD FULLER, M.B., B.S. DURH., M.R.C.S. ENG.,
LATE SENIOR RESIDENT MEDICAL OFFICER TO THE BIRMINGHAM CHILDREN'S HOSPITAL;
AND
F. R. GIBBS, M.R.C.S. ENG., L.R.C.P. LOND.

THE case about to be described is, perhaps, more interesting as a curiosity than as a contribution to medical literature, but the fact that a murmur of such intensity should occur in a subject whose actual cardiac disease causes so few inconvenient symptoms is sufficient excuse for the few notes here appended. The patient, a bright and intelligent school girl aged fifteen years, belongs to a family many members of which suffer either from phthisis or cardiac disease. Her personal history is good. She has never suffered from any serious ailment and has always enjoyed fair health. The cardiac mischief causes no other symptom than the fact that she easily gets "out of breath." The heart is not enlarged or dilated, there is a good first sound, followed immediately by a murmur and a low second sound. The murmur is mitral, and this is the interesting feature of the case, for it can be heard when the patient is fully dressed at a distance of twelve feet or more. It can also be heard when with the chest exposed she is placed three feet away from a closed door and the listener is at the same distance on the other side in the hall. As might be expected, the murmur varies somewhat in intensity from day to day, but it is only very rarely that it cannot be heard a foot away from the chest without the stethoscope. We believe this to be unique.

"LANDRY'S PARALYSIS FOLLOWING INFLUENZA."

BY J. C. BOWIE, M.B., C.M. ABERD.

A CASE somewhat similar to the one referred to in the annotation under the above heading in THE LANCET of Feb. 29th has come under my care; the type of influenza differs, as does also the severity of the subsequent paralysis.

The patient is a lad aged seventeen years who was exposed to wet on Jan. 15th, 1896. The next day he had an attack of influenza, marked by the sudden onset of feverishness, depression, cough, and a slight amount of soreness of the throat which lasted only for a day. From Jan. 19th to Feb. 1st he travelled a good deal by sea, and was several times exposed to cold in a small boat. On Feb 1st he made one of these voyages which lasted nine hours in an open boat, and in the evening was seized with great feebleness, especially of the lower extremities, with numbness of the feet; and vomiting occurred. A slight amount of pain was felt in the back and head. Loss of appetite accompanied the depression. The feebleness increased for two or three days, so that the body was affected generally and also the arms, the right side rather more so than the left. The grasp of both hands was weak. There was a difficulty of lying on the right side from a feeling of soreness—this lasted four weeks. The heart's action was slow and feeble, but otherwise natural. The temperature was subnormal; the knee-jerks were lost; there was no difficulty in swallowing; the speech was somewhat slower than natural, but this might only be due to depression. On the 10th the temperature was normal (98·6° F.), but otherwise the patient's condition was unchanged. Soreness was felt on kneading the muscles of the limbs. There was slight sensory impairment in the feet. From the 15th to the 24th the bowels became more inactive and refused to react to laxatives, and laterally became loaded. On the latter date injection by enema was resorted to, followed by a dose of croton oil, and since then no difficulty was experienced. About this time, also, the urine was longer retained and consequently more copious at a time, but no paralysis occurred. Gradual improvement in muscular power occurred during that time, being still more marked during the following week. Appetite was regained, and since then slow but gradual improvement has taken place. On March 18th the knee-jerks showed a slight reaction after a long period of latency. The patient on the 27th was able to stand, but feebleness of the limbs was still present, so that he was not able to stand for any length of time.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

ST. THOMAS'S HOSPITAL.

TWO CASES OF OBTURATOR HERNIA, ONE BILATERAL; REMARKS.

(Under the care of Mr. WILLIAM ANDERSON.)

OBTURATOR hernia is one of the rarities of surgical practice. Only one case appears in the surgical reports of St. Thomas's Hospital from 1870 down to the date of the two examples now related, and only thirty operations are known to have been performed in Europe down to the present day. Case 1 appears to be the only example reported of bilateral obturator hernia treated by operation. Case 2 illustrates the extreme difficulty in the way of diagnosis before operation in some examples, and it points strongly to the disastrous consequences of delay in calling for the assistance of the surgeon in obscure conditions of intestinal obstruction. There is little doubt that the patient's life would have been saved could the operation have been done a day earlier. For the notes of Case 1 we are indebted to Mr. E. H. Cobb and for those of Case 2 to Mr. Everett Millais.

CASE 1.—The patient, a woman aged seventy-one years showing the usual senile emaciation but of fair power and vitality, had been suffering for the last seven years from occasional attacks of intestinal obstruction, accompanied by pain on the inner side of the left thigh and some fulness in Scarpa's triangle; the symptoms disappearing at the end of a day or two and leaving no ill-effects. During the last two years a local prominence had been noticed below the groin. On Nov. 24th, 1895, symptoms of strangulation set in without obvious cause, and the patient was sent to St. Thomas's Hospital three days later. There were then signs of obstruction, indicated by constipation, vomiting, and prostration, and a tender swelling as large as a walnut was found over the position of the left obturator foramen, and complaint was made of pain radiating along the inner side of the thigh. The tumour was deeply placed on the inner side of the femoral sheath in a position a little below and internal to that of a femoral hernia; it was most visible when the thigh was extended, and most easily palpable when the limb was flexed, adducted and rotated outwards, and was then felt as a tense rounded mass irreducible and free from impulse on coughing. On examination per vaginam a slight fulness on the left side could be distinguished in the direction of the obturator canal. Nothing was observed on the right side. The condition was diagnosed as strangulated obturator hernia, and an operation was performed without delay. An incision about two and a half inches in length was made over the tumour, downwards from the level of Poupart's ligament for about two and a half inches on the inner side of the femoral sheath; the pectineus muscle was exposed and its fibres were separated and held aside with retractors, exposing what appeared to be the sac of a hernia about an inch and a half in diameter. This membrane was of a dull white and as thick as a sheet of stout parchment. It was incised, and beneath and somewhat adherent to it appeared the true peritoneal sac. This was laid open and after the escape of a little reddish serum a small knuckle of intestine was visible. It was deeply congested, but retained its lustre and was not adherent to the sac. Its neck could be traced into the obturator canal and appeared to be nipped below by a semilunar fibrous band in the position of the external obturator membrane. A director was then passed into the canal below the intestine for nearly an inch, and the constriction was divided for about a sixth of an inch in a downward and slightly inward direction with a bistoury. No hæmorrhage followed. The intestine, after a brief inspection, was then emptied and returned without difficulty. The sac was next isolated from the surrounding tissues and twisted, and a ligature was tied around it as far within the canal as possible. The thread having been cut and the superfluous portion of the sac removed, the stump was pushed well into the pelvic cavity and the wound was closed. In the course of the operation the pulsation of the obturator artery could be distinguished at the upper and inner part of the canal. The nature of the membrane covering the sac could not be determined. It appeared to be quite free from muscular fibres and detached from the pectineus muscle. The operation was well borne. All symptoms of obstruction disappeared and at the end of a week the wound was found to be healed. The patient regained strength rapidly, but complained from time to time of neuralgic pain along the course of the obturator nerve.

On Dec. 22nd, twenty-six days after admission, a hernia appeared on the opposite side, but vanished spontaneously at the end of a few hours. Four days later, however, it returned, in company with sickness and other signs of obstruction, with considerable prostration of strength. The tumour was almost identical in its size, position, and character with that on the left side, but was less tense and tender. A second operation was performed in the same manner as before. The sac was found beneath a thick fascial covering, as on the left side, and on opening it the exposed small intestine appeared almost uninjured and was reduced without further use of the knife. The sac was isolated and ligatured and the wound was closed. The progress was again favourable and the patient made a good recovery except for the appearance of a small sinus apparently due to suppuration around a stitch. The patient was fitted with a double truss, with fixed semi-elliptical pads each so adjusted that its straight edge lay over the pectineus muscle parallel to the femoral sheath.

CASE 2.—The patient, an emaciated woman of cachectic aspect, was admitted on Dec. 9th, 1895, with symptoms of intestinal obstruction. She was in a state of extreme prostration and the history was difficult to obtain. She said she had been suffering from constipation and abdominal pain for five years, with frequent diarrhœa and pain referred to the umbilicus and vulva; the motions were usually scybalous, and no blood had been seen in the stools. Five months ago the bowels were constipated for three weeks, but were at length relieved under purgative treatment. A week before coming to the hospital acute symptoms of obstruction set in and the vomited matters had a strong fæcal odour. On admission she was extremely prostrate. The abdomen was but moderately distended, and no tumour could be felt either at the hernial apertures or within the abdomen by rectal or vaginal examination. An immediate laparotomy was decided upon. The abdomen was opened and a long coil of contracted small intestine was exposed, but before this could be traced to the point of obstruction the pulse stopped and the patient died. It was noticed that a peritoneal pouch extended into the right obturator foramen large enough to admit the tip of the forefinger for about three-quarters of an inch, and it was thought probable that the seat of obstruction would be found in the opposite obturator canal. At the post-mortem examination a knuckle of small intestine was found strangulated in the left obturator canal, not reaching to the anterior opening. It was not gangrenous, and the constriction involved only about two-thirds of the circumference of the gut.

Remarks by Mr. ANDERSON.—The obturator canal has received inadequate attention in our anatomical text-books, but a most elaborate essay upon the Anatomy and Surgery of Obturator Hernia by Piqué and Poirier[1] almost exhausted the subject down to the dats of the articles. This was preceded by an equally painstaking monograph by Englisch.[2] The obturator canal may easily be studied in the dissecting-room by a simple sagittal section through the pelvis at a point about an inch external to the pubic spine. From such a section the accompanying figure has been copied. A reference to it will show the canal as a passage about an inch in length, bounded in front[3] by the body of the pubic bone and behind by the

[1] Piqué et Poirier: Étude sur la Hernie Obturatrice. Revue de Chirurgie, 1891, Nos. 9 and 11, and 1892, No. 4.

[2] Josef Englisch: Über Hernia Obturatoria, Wien, 1891.

[3] This description implies that the pelvis is placed in the position of station (i.e., with the axis of the brim forming an angle of from 150° to 155°, with a vertical line falling upon the promontory of the sacrum). The plane of the obturator foramen is then seen to form an angle of about 30° with the horizontal, and the obturator canal lies behind the body of the pubic bone, and below it only to a slight extent at its femoral extremity.

Digitized by Google

external[4] and internal obturator membranes and muscles. In the female it is usually large enough to admit the little finger and becomes still larger when the soft structures undergo senile atrophy; in the male it is narrower. These peculiarities will explain the great relative frequency of the condition in women of advanced years. The direction of the canal is chiefly downwards, with an oblique inclination inwards and forwards, but towards its lower or crural end it curves forwards at an angle of about 45° with the horizontal. The nearly vertical direction of the inlet of course favours the occurrence of hernia when the other conditions are favourable. The posterior wall of the canal presents two branch passages, one (K) running backwards between the two obturator membranes, the other (I) downwards, traversing the fibres of the

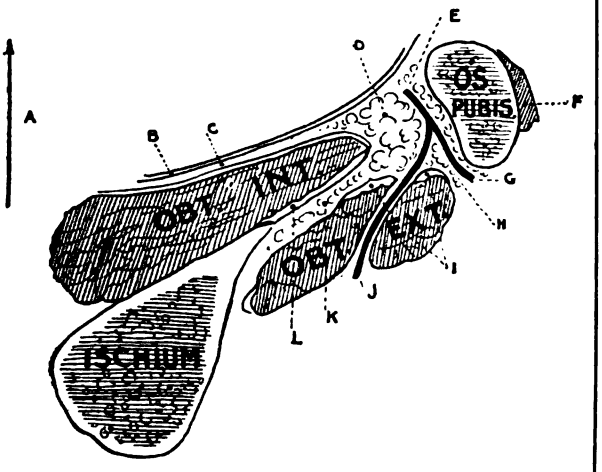

Diagram of the obturator canal, from a preparation in St. Thomas's Hospital. A, Longitudinal axis of body. B, Parietal peritoneum. C, Sub-peritoneal tissue. L, Internal obturator membrane.

obturator externus and transmitting the posterior division of the obturator nerve as well as some small collateral vessels. These diverticula are important to note because an obturator hernia may enter either. The canal is closed on the pelvic side by the parietal peritoneum, which is usually stretched more or less loosely across the inlet; and on the crural side by the pectineus and adductors. It transmits the obturator vessels (arteries, veins, and lymphatics) and nerve, and contains a mass of adipose tissue, which is continuous above with the subperitoneal plane of fat and sends processes into the space between the two membranes, and even through the canal for the posterior division of the obturator nerve. When this fat becomes absorbed during the senile involution of tissues, the parietal peritoneum is apt to be drawn or pushed into the pelvic orifice of the canal as a pouch of varying depth and width, and the way is thus prepared for a hernia. Such a condition was found on both sides in Case 2 and is occasionally met with in the dissecting-room. The course that may be followed by a hernia is obvious: (1) it may remain within the main canal and yet as in Case 2 may become fatally strangulated; (2) it may pass into the passage between the two obturator membranes and, as in the last, may lead to no appearance of a tumour in Scarpa's triangle; (3) it may enter the inter-muscular cleft for the posterior division of the obturator nerve and so reveal itself as a deeply placed tumour externally; or (4) lastly it may complete the transit of the canal and project beneath the pectineus as in Case 1, or if sufficiently large may wander wherever the inter-muscular spaces will permit. According to Fischer a hernia may also run outwards between the external obturator membrane and the cotyloid notch, but it is doubtful whether this variety, although possiole, has been demonstrated.

[4] The external obturator membrane of Fischer is a fairly strong plane of fibrous tissue attached in front to the lower border of the pubic bone and behind approaches the middle of the internal obturator membrane (the obturator membrane is over that body). The two membranes are separated by a space containing fat. See figure.

Practically we need only consider the varieties named, but it is possible, though scarcely profitable, to subject each to minute sub-division, as in the classification formulated by Englisch. The anatomy of the obturator vessels and nerve is well known. It is only necessary to note that the obturator artery, when it arises normally from the anterior trunk of the internal iliac, will enter the canal below the nerve, while if it spring from the deep epigastric it runs close to the anterior or bony wall, each arterial branch accompanied by large venæ comites. The relation of the obturator canal to the pelvic cavity will indicate the probabilities as to contents of the hernial sac. The small intestines are always in close relation, and hence in over 91 per cent. of the recorded cases it is a coil of gut or a portion of a coil that finds its way into the canal. Next in order of frequency come the ovaries and Fallopian tubes, about 4 per cent. The uterus appeared in the sac in one case and the vermiform appendix in one. The great omentum is seldom found. From the constitution of the canal strangulation is proportionately less common than in inguinal or femoral hernias, but the history of some of the examples, as in Case 1, shows that passing attacks of incarceration are not infrequent, while owing either to peristalsis set up by purgative treatment or to the effect of the distension of the proximal portion of the gut above the constriction, the intestine is drawn out and relief occurs without surgical intervention. The signs of strangulation do not always clearly indicate the locality of the mischief. They may be analysed as follows:—1. Obstruction of the bowels, with the ordinary symptoms of the condition. 2. An external tumour in Scarpa's triangle, below Poupart's ligament, beneath the pectineus, and on the inner side of the femoral ring. It is most visible when the limb is extended, and most easily palpable when the muscles are relaxed by flexion and internal rotation. It will, however, be absent when the hernia lies within the canal or between the obturator membranes, or may be difficult to detect even in the complete form if, as rarely happens, the patient is very fat. 3. Internal indications of tumour by vaginal or rectal examination, as found in Case 1. 4. Tenderness on firm pressure with the finger tip in the region of the external opening of the obturator canal may assist diagnosis when there is no palpable tumour. 5. Irritation of the obturator nerve commonly accompanies incarceration as well as strangulation. It is shown chiefly by a neuralgic pain extending along the inner side of the thigh, and even to the knee or lower, and sometimes by a sense of stiffness or cramp in the adductors. In some instances, as in Case 2, the characteristic indications localising the seat of obstruction may all be absent. As a rule, however, an intestinal obstruction of obscure origin in an old and emaciated female should always lead to a careful examination of the external opening of the obturator canal before abdominal section, and an exploration of the internal opening afterwards when laparotomy is performed. Thirty operations for the relief of strangulation have been recorded, including those now described. Of this number sixteen ended fatally. Laparotomy was performed in five. In the fatal cases twelve deaths were due to the injury to the gut (gangrene perforation) by the strangulation, and could hence scarcely be attributable to the operation. The method of kelotomy is usually that adopted in the case now reported. It offers no difficulty, and almost the only risk for which the surgeon is likely to be responsible is hæmorrhage from a wound of the obturator vessels—a dangerous complication owing to the difficulties opposed to the arrest of the bleeding by the depth and inaccessibility of the source. The artery usually lies opposite the upper and outer part of the sac (in Case 1 the pulsation was distinctly felt above and internally), and a section of the constricting band in connexion with the external or internal obturator membrane may usually be made with safety in a downward and slightly inward direction. The incision should, however, be as short as possible. It would, perhaps, be still safer to introduce a steel director or some other strong edgeless instrument beneath the neck of the hernial sac and widen the opening by forcible pressure in a downward direction. This would involve no risk and would probably be sufficient to allow reduction. An attempt at radical cure will, of course, always be made after reduction. It is doubtful whether anything is feasible beyond ligature of the neck of the sac as high as possible. When a kelotomy reveals a gangrenous state of intestine the problem is similar to that offered by the same condition in other herniæ. An attempt to excise the

Digitized by Google

gangrenous portion and to suture the two ends may not often be advisable; and probably the best practice, where the patient's condition permits, will be found in a laparotomy and the establishment of a lateral anastomosis between the two portions of the strangulated coil on the abdominal side of the canal. It is hardly necessary to press the advantages of promptitude when operation is found necessary. The mortality is that of delay, not of surgery. Taxis has been successful in a certain number of cases of strangulated obturator hernia, but in the present day this measure would be used with great caution if at all. Any persevering efforts at reduction by this means would be likely to increase the fatality of the condition.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Tuberculous Kidney.—Series of Cases of Enterectomy, with Remarks on the Various Methods Employed in Securing Union of Divided Edges of the Hollow Viscera.—Successful Suture of a Duodenal Ulcer.

AN ordinary meeting of this society took place on March 27th, Dr. BUZZARD, President, being in the chair.

Dr. F. J. SMITH and Mr. L. BIDWELL read the notes of a case of Tuberculous Kidney, for which nephrectomy was successfully performed.

Mr. MAYO ROBSON gave the details of a series of cases of Enterectomy, with Remarks on the Various Methods Employed in securing Union of Divided Edges of the Hollow Viscera. He remarked that the whole of his personal experience of enterectomy was furnished in the table of cases, twelve in number, which he handed round; and that by the kind permission of his colleagues he had been able to add the whole of the enterectomies which had been performed in the Leeds Infirmary to the table, which thus represented a series of twenty-six cases, on which his arguments were based. He divided the series into three classes. 1. Those operated on by simple suture, nine in number, of which five died, yielding a mortality of 55·5 per cent. 2. Those operated on by the Murphy button, five in number, of which one died, giving a rate of mortality of 20 per cent.; two had had fistulæ and a retarded convalescence, and in one the button had not passed while the patient was under observation. 3. Those in which a decalcified bone support in the shape of a button or some similar contrivance was employed to support the sutures, of which there were twelve cases with one death, giving a rate of mortality of 8 3 per cent. After remarking on the disadvantages attending simple suture, such as multiplicity of stitches required, the danger of stenosis, and the fear of infection through the needle punctures, and after mentioning the advantages of Maunsell's method in intussusception and its disadvantages in other forms of enterectomy, Mr. Robson referred to the use of the Murphy button, which he said he preferred for cholecystenterostomy and for short circuiting in intestinal obstruction, but which he thought had great disadvantages in enterectomy. He mentioned cases where the button had caused ulceration, where it had produced obstruction, and where it had never passed; he also dwelt on the necessary pressure-necrosis and the fear of gangrene spreading beyond the parts embraced, leading to perforative peritonitis, or in case of recovery to after-contraction in the newly-established fistula. Mr. Robson said that before all other methods he preferred to suture the intestine by a continuous stitch and to support the line of union by a hollow decalcified bone bobbin, the safety of which he thought he had proved by the list of cases given in the paper and by the rate of mortality being reduced so low as 8 per cent. The advantages he claimed were a saving of time from the use of only one or at most two stitches; the prevention of subsequent stricture by the establishment of a continuous mucous canal; the perfect security against leakage; the absence of a foreign body in the intestine, as the bone dissolved when its work was done; the prevention of infection of the line of suture; the immediate continuity of the newly-made canal; and, lastly, the applicability of the bobbin to any of the operations required for the establishment of continuity of the intestinal canal. After describing, by the aid of diagrams and models, the operation he generally adopted he said that though it might be more ideal to do without any mechanical aids in these operations it was incumbent on the surgeon to carefully study the advantages and disadvantages of the different procedures before adopting any method because it was supposed to be the ideal one.—Mr. B. JESSETT expressed his regret that Mr. Robson had not alluded to Senn's papers on uniting the intestine by bone plates, the experiments establishing the utility of which were first repeated by himself in this country. Mr. Paul of Liverpool was the first to make a definite improvement upon Senn's method, then followed Maunsell's operation, which was one of the best. Murphy's button looked simple, but required delicate manipulation for successful application; if the button dropped back into the stomach it might prove the cause of ulceration and perforation later on. Of five cases he had adopted Maunsell's method in three and that of Robson in two. They had all recovered except one of excision of a portion of transverse colon for cancer by Maunsell's method. In one instance he had performed both Maunsell's and Robson's operations for two different fæcal fistulæ on the same patient, and both with a successful result.—Mr. W. G. SPENCER said that Czerny of Heidelberg had published an equally good series; the suture employed being practically the same but no bobbin being used. He inquired if Mr. Robson had used a potato or turnip out of which to fashion a bobbin; also whether he had used the bobbin with success on parts of the intestine incompletely covered or not covered with peritoneum.—Mr. H. ALLINGHAM referred to his paper before the Medical Society of London in which he related the fatal results which had followed the operation if the gut were distended at the time. He was sure that the use of some form of internal splint was of great assistance to the operator. At St. George's Hospital every time Murphy's button had been used the patient had died.—Mr. F. BURGHARD said that he had operated twice by Maunsell's method and four times with Murphy's button. He resected the cæcum for malignant growth about the ileo-cæcal valve and united by means of Maunsell's method, the patient being at the present time living and well two and three-quarter years after the operation. In a case of malignant disease about the beginning of the sigmoid flexure the patient died of perforation on the eleventh day. In that case there was no mesentery and he found it extremely difficult to carry out Maunsell's invagination. In two of his cases in which he used Murphy's button the patients died almost immediately of shock, and therefore the result of the use of the button could not be ascertained. In a case of pylorectomy the patient did well, though he died from recurrence seven and a half months after the operation. The operation was completed by the aid of the button in forty-five minutes and the button was passed on the thirty-fifth day. In the case of malignant disease of the descending colon Murphy's button was used and the patient did well being at the present time alive and with no recurrence.—Mr. BOWLBY remarked that Maunsell's operation was easy of performance upon undistended intestine, but he had tried it in a case of gangrenous hernia and found that it was extremely difficult to invaginate the gut. The patient died from peritonitis, from leakage at the stitch holes, and the lumen of the gut he found afterwards was almost occluded by the in-turned portions of the coats of the bowel. The free passage ensured for the immediate transit of fæces and flatus was not one of the least important merits of Mr. Robson's plan.—Mr. CLUTTON asked if Mr. Robson had considered the advantages of lateral anastomosis. In his own hands it had been eminently successful. He had also found that Murphy's button gave good results, its chief cause of failure appearing to be that it did not pass. In end-to-end approximation of gut he had had successes, but he had also had a large number of failures.—Mr. MAYO ROBSON, in reply, said that his paper only alluded to personal experiences and hence he had said but little of Senn's plates. Maunsell's method was excellent for intussusception, and he would like to remark that his colleague, the late Mr. McGill, suggested the details of this operation years before Maunsell brought it out. The outer line of suture should be passed through the outer coats of the bowel only, whether peritoneum or not. He agreed that there was danger in operating upon distended intestine, but in many cases there was great objection to an artificial anus, especially where the opening had to be made into the small

Digitized by Google

bowel. The disadvantage of lateral anastomosis was that it gave three lines to suture up instead of one. He had suggested to Dr. Murphy that the distal flange of the button should be made larger, so as to prevent it travelling into the stomach or proximal part of the gut.

Mr. L. A. DUNN read notes of a case of Successful Suture of a Duodenal Ulcer. The patient whilst at work felt a sudden pain in the epigastrium, attended with nausea and faintness. He was taken home and subsequently to Guy's Hospital on Aug. 2nd, 1895. The abdomen was distended and remarkably tympanitic. The normal hepatic dulness was absent. He was suffering great pain and had an anxious expression of countenance. The abdomen was opened by median incision above the umbilicus, which allowed of the escape of a quantity of gas and yellowish fluid. A small perforation was found in the anterior wall of the first part of the duodenum. This was closed with five silk Lembert sutures and the abdominal cavity flushed out with boiled water. The flushing process interfered with respiration and so could not be thoroughly carried out, hence a Keith's tube was put into the upper parts of the wound for the first twenty-four hours. The patient progressed well for ten days, when his pain returned and his temperature was raised. He became worse till Aug. 27th, when the abdomen was opened a second time, on this occasion along the right costal margin, as it was thought that a collection of pus had formed between the liver and the diaphragm. Nothing was discovered except a few adhesions in this region, chiefly beyond the reach of the finger. An exploring needle passed through the eighth intercostal space was felt to traverse the abdomen and perforate these adhesions. A drop of pus was evacuated by this method. The wound was closed, the intention being to open and drain the abscess through the thorax at a later date. This was not, however, required as the temperature fell immediately after the operation, and remained low till the sixth day, when the wound was found to be distended with pus. The removal of two sutures sufficed to evacuate this, after which the recovery was rapid.—Mr. BLAND SUTTON said that some years ago he was interested in the subject of duodenal ulcers and looked up the cases. They occurred mostly in males past mid-life, and they had, he was sure, a different pathology from the gastric ulcers of chlorotic girls. They appeared to occur generally in subjects addicted to ardent spirits. The proper temperature to flush out the abdomen was 110° to 115° F.; if water colder than that were used shock would be induced, particularly in flushing out the upper regions of the abdomen.—Mr. DUNN, in reply, said that he had often used water at the temperature of 100° F. to flush out the abdomen, but he had never before seen such an effect produced on the respiration.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

Some Factors in our Atmospheric Environment and their Relation to Health.—Modern Improvements in British Balneological Practice.

AN ordinary meeting of this society was held on March 4th at Limmer's Hotel, Dr. HENRY LEWIS, the President, being in the chair.

Dr. HENRY MCCLURE (Cromer) read a paper on Some Factors in our Atmospheric Environment and their Relation to Health, dealing with the composition of the atmosphere, its temperature, movements, and other conditions, and the phenomena produced by electricity and sudden changes of weather in human beings. He finally spoke of sunlight, its action on bacteria, and the probability that the ultra-violet rays penetrate below the surface of the skin. He believed that sunlight had a bactericidal effect due to the ultra-violet rays.

Dr. DOUGLAS KERR (Bath) then read a paper on Modern Improvements in British Balneological Practice. After stating that the application of water in the form of baths as a hygienic measure had been recommended for many ages, he discussed the origin of springs, the cause of their occasional high temperature, and the inherent property peculiar to each spring independently of its chemical composition, so that in selecting any one spa for any particular disease a medical man should be guided not so much by the mineral ingredients contained, unless present in very large amount, but by the combination of ingredients, and especially gaseous constituents, by the general character of the water as regards hardness or softness, by its effect on the system generally, and, above all, by the recorded evidence of credible witnesses as to its power in effecting cures. On the Continent for at least half a century thermal treatment had been steadily improved by scientific modes of application and had been recognised as an efficient treatment for some diseases which were not very amenable to drugs, while till within the past few years the English watering-places had been trusting to the obsolete modes of bathing handed down from former generations. Happily, all this was now changed, for at several English health resorts arrangements have already been or are being made for providing facilities for special treatment on the lines adopted at Aix-les-Bains and other Continental spas. He described various details and finally spoke of the Nauheim treatment as being carried on at various British spas.—Dr. MYRTLE (Harrogate) confirmed what Dr. Kerr had said about the immense improvements that had taken place with respect to baths in this country. At Harrogate they now had baths of almost every kind and all the arrangements were excellent.—Dr. GIFFORD BENNET (Buxton) said that during the twenty-seven years he had been physician to the Devonshire Hospital he could not remember a single fatal case occurring there during the whole of these years from the use of the baths. The only reason he could give was that every case received into the hospital was thoroughly and carefully examined. Some of the other cases who did not go from the hospital were examined, but on the other hand a large number went to the baths without any such preliminary precaution. They came to Buxton as to other spas, thinking that it was an ordinary water, and then plunged in, the consequence being that in some cases death took place.—Dr. EARDLEY-WILMOT (Leamington) considered that patients should be placed under the care of a medical man at the health resorts to which they were sent. He had known serious results happen to people who took these baths without this precaution and sometimes even without consulting a medical man in their own neighbourhood.—Mr. HOLBECHE (Malvern) said he had come to that meeting specially to get some authoritative opinion with regard to the Nauheim treatment of heart complaints by balneo-therapy. He could understand that the action of a hot bath and movement of the muscles might, by producing "fluxionary hyperæmia," relieve congestion of the right side of the heart; but he could not understand how reflex action of the skin or absorption of carbonic acid gas by the pores of the skin could be of any practical value in the treatment of heart complaints.—Dr. SNOW said that on this question of the treatment of the heart by this method he felt bound at the present time to take up a neutral position. Sufficient facts had not been put before them by independent observers to show the benefits which Dr. Bezly Thorne and others had mentioned as following that treatment.—Dr. LOUIS BLANC (Aix-les-Bains), speaking at the invitation of the President, expressed his pleasure at hearing of the reputation of the British baths. Many improvements had now been introduced in them, as he could personally testify from recent visits to Buxton and Harrogate. The practice of massage and the different methods of douching had special actions on the body, as in the treatment of rheumatism, but the waters themselves had something to do with the result apart from special appliances. Patients who went to these baths had often undergone massage and other treatment in London, Paris, and other large towns, where good accommodation and every convenience and modern improvements were to be had, but the effect produced had been but slight compared with that obtained at the mineral spas.—Dr. SEPTIMUS SUNDERLAND regretted that the details of the different modern improvements had not been gone into more fully. The rapidity with which the Nauheim treatment seemed to have taken hold of the profession upon very slender evidence reminded him of the Koch lymph craze a few years ago. He himself had no experience of the treatment, and while among the cases of which he had heard there had been some excellent results two had been disastrous.—Mr. SHIRLEY JONES (Droitwich) said that they had tried the Nauheim treatment on a few cases at Droitwich, but he was not in a position to specify definite results. He could not say whether it would or would not prove a success, and he considered that it would be premature to make any definite arrangements for it.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

The Better Regulation of the Out-Patient Department.

A MEETING of this society was held on March 18th, Dr. W. B. RANSOM being in the chair.

Dr. KINGDON, in a paper on the Better Regulation of the Out-Patient Department, advocated the adoption of a uniform system of enumerating the total number of out-patients at each hospital. For instance, the same person on obtaining a fresh recommendation was often counted as a "fresh case." Patients coming from the country should be distinguished from those belonging to the town. Reference was made to the great variation in the number of patients in different towns where similar causes might be supposed to operate. Among the causes of the evil arising from unsuitable applications for treatment the recommendation system was specially condemned as favouring that which it was intended to avert. The Hospital Saturday and Sunday organisations, together with the fact of out-patients being prescribed for by an honorary staff, tended to increase the number of out-patients. The failure of the attempts made in different towns by committees of inquiry to reform the out-patient department was ascribed to too much having been attempted, and to the recommendations being overburdened with suggestions as to the formation of provident institutions and the like. It was suggested that suitable applicants were: 1. Those whose wages and that of the family were below a fixed standard. 2. Those whose wages exceeded the standard, but who had already paid a private medical man as long as they could afford. Both these classes were entitled to continuous attendance. 3. Those frequenting the hospital as a public consulting-room—e.g., members of sick clubs or those referred by a medical man. These should be seen once and the written opinion of the consultant forwarded to the medical attendant. The abolition of the recommendation system was advocated, also that the onus of proving their suitability should be placed on the applicants themselves; that each hospital should appoint an inquiry officer, male or female, who would interrogate each patient from printed questions; and that the answers should be written down by the officer and signed by the patient, and a distinguishing mark placed upon the prescription paper before the patient was seen by the medical staff. All unsuitable applicants should be at once rejected by the inquiry officer.

Dr. BOLTON thought public dispensaries unnecessary; the poor should be medically treated either by hospitals or the parish.

Further observations were made by Dr. RANSOM, Mr. MACMILLAN, Dr. WATSON, Mr. PRYCE, Mr. LANDER, Mr. STEPHENS, Mr. WILLIAMS, and Dr. MUTCH.

LIVERPOOL MEDICAL INSTITUTION.

Roentgen's Radiography.

A MEETING of this society was held on March 26th, Dr. RICHARD CATON, President, being in the chair.

Professor OLIVER LODGE (on the invitation of the President) gave a most interesting lecture on the Roentgen Radiography and its application to Medicine. He first traced the history of the subject previously to the discovery of Roentgen, calling attention to the researches of Crookes, Hertz, and Lenard, describing their methods and the extent to which their researches reached. He illustrated this part of the lecture by showing their instruments and repeating their experiments. He then explained the theory of the production of the rays and said that there were three different forms of rays proceeding from the kathode; each of these rays had its special properties. He then exhibited a screen prepared by Dr. Kohn with potassium tungstate. By means of a focus tube and a very powerful coil he projected on this screen shadowgrams of various objects, which were clearly seen by the audience. The objects consisted of a number of instruments in a wooden case, the hand and elbow joint of an assistant, and many more. With a magic-lantern he then showed upon a screen Radiographs of a sprained wrist, a dislocated thumb, a needle in a hand, and many other interesting pictures. Some excellent radiographs were handed round for members to examine; amongst the most interesting were a representation of the spine of a young woman who had sustained a fracture of the spine by falling out of a window, and one of a Murphy's button which had been retained for a long time in the abdomen of a women on whom an operation had been performed, the button having never come away. The position of the button was well seen.

A cordial vote of thanks was accorded to Professor Lodge for his kindness in giving the lecture, after which the meeting terminated.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

Exhibition of Cases and Specimens.

THE closing meeting of the present session of this society was held on March 12th in the Royal Infirmary, Newcastle-upon-Tyne, Dr. J. DRUMMOND, the President, being in the chair.

Dr. OLIVER and Mr. WILLIAMSON showed a youth aged seventeen years who had on three occasions hurt his head, one of the resulting scars being above the right ear opposite the face centre. For two years he had frequent attacks of *petit mal* and then a distinct epileptic convulsion preceded by severe headache. After admission to the infirmary he was delirious and had fits during the night. Double optic neuritis passing into atrophy was present. The fits always commenced on the left side of the face, passed to the left arm, then to the corresponding leg, and finally became general. A small hole was drilled over the face centre with the brace and bit trephine, and the skull was chipped away with cutting forceps over the motor area, but nothing was found, and though surgically the case did well the result was negative so far as the fits and the mental condition were concerned.

Mr. PAGE showed six men who had been operated on during the past year for Internal Derangement of the Knee-joint. In all the cases except one the result was perfect, for a freely movable, strong, and painless joint had resulted. The unsuccessful case was in a patient fifty years of age suffering from rheumatoid arthritis of the joint, which was opened and partially "erased" in the hope of benefiting him. He was no better and no worse for the operation. In each of the five successful cases the internal semilunar cartilage was excised through a transverse cut over it on the inner side of the knee, and in every case the wound healed by first intention.

Dr. DAVID DRUMMOND showed two men (miners) suffering from Leukæmia. One was fifty-four years of age and was first admitted into the infirmary in January, 1895, six weeks before which date he noticed himself becoming weak, breathless, and pale, and shortly before admission he discovered a swelling in his abdomen. His spleen was much enlarged, his legs were swollen, and his blood showed one white to six red corpuscles. There was a large amount of white uric acid in his urine, and a cardiac systolic murmur in the mitral area. He improved in general condition under arsenic, his blood at last contained one white corpuscle to 7·03 red corpuscles, and he was discharged. Seven months later he was readmitted, and his spleen then filled the left hypochondrium and reached to the umbilicus. His blood at present contains one white corpuscle to 4·7 red. The second patient was a man aged forty-five years whose spleen was large and whose blood contained one white corpuscle to four red corpuscles. An examination of the serum from the swollen legs of both men showed the presence of a large number of white cells (leucocytes) which were not found in the serum in heart or kidney cases. So far as Dr. Drummond knew this observation had not been made before. Both of these cases were examples of the spleno-medullary form of leukæmia, and the so-called myelocytes of Ehrlich (i.e., large uninucleated neutrophiles), the presence of which alone proves this form of leukæmia, were demonstrated.

Dr. GEORGE MURRAY showed a man, forty years of age, suffering from Hodgkin's Disease. When fourteen years old he first noticed that two of the lymphatic glands in his left axilla were enlarged and they have remained unaltered. A year ago the inguinal glands were noticed to be similarly affected, and a swelling was discovered two months later in the left side of the abdomen. Six months ago the enlarged inguinal glands softened, increased in size, and yielded a discharge for a time. Two months ago he noticed his skin

Digitized by Google

darken. With the exception of some weakness he has felt nothing wrong. The inguinal glands now form tumours the size of cocoa-nuts, but the sinuses are healed. The axillary and cervical glands are large and hard, the spleen is much enlarged, and a nodule the size of a billiard ball can be felt immediately below its notch (probably a lymphadenomatous growth). In the blood there is one white corpuscle to 200 red corpuscles. Arsenic had not materially benefited him.

Dr. HUME exhibited a patient who had recovered from an operation for an abdominal tumour which proved to be a Lymphangioma of the Mesentery, and another on whom a successful operation had been performed for Intussusception with protrusion of the ileo-colic valve through the anus. He also gave a description of seven cases under his care now convalescent after operations for Appendicitis, and showed a man who had suffered from Free Internal Hæmorrhage, arrested after drainage and constant pumping. The patient had fallen from a height of thirty feet. At first his symptoms were not urgent, but at the end of twenty-four hours his abdomen was swollen and tense with fluid and he vomited everything. An incision was made in the right linea semilunaris and the peritoneum and pelvis were found full of blood, which was washed out, but search failed to reveal the bleeding point. A drainage-tube was left in and pumped out every half hour. Fresh bleeding followed the operation, but gradually ceased, and the patient made a perfect recovery.

Reviews and Notices of Books.

Mental Physiology, especially in its Relation to Mental Disorders. By THEO. B. HYSLOP, M.D. Edin. Pp. 552, one vol. London: J. & A. Churchill.

THIS work is, as its title indicates, intended especially for candidates for the M.D. at the University of London, but it is not merely a text-book, for the author takes a strong position of his own on many of the points which are still discussed on this very debatable ground. It is evident that a vast number of authors have been consulted and in most particulars the work is quite up to date. That it completely fulfils its object can scarcely be said. It is, indeed, difficult to see how one book can in such a subject be successful, for the many views held as to the nature of matter, the explanations ventured as to modes of brain action, theories as to the connexion between mind and brain, &c., are studies in themselves that can only be grasped by prolonged consideration, and, therefore, we think that whilst Dr. Hyslop's book is of considerable value to the teacher who wants to summarise his knowledge it will be found too concentrated for the student, there is in it too much pemmican for the imperfectly (in this subject) trained organs of the ordinary candidate. Mental philosophy is of all subjects the one that requires gradual elaboration, and to be suddenly thrown into the thick of abstruse and conflicting theories is to say the least confusing, and though Dr. Hyslop evidently sees this difficulty and endeavours to clear up the speculation by a dictum here and there, the process is not always to be readily seen through by the student. It is doubtful if complete success in the production of one single volume embracing the necessary psychological training with the adjustment of this to insane conditions is possible, because in the face of the new physical experiments that are constantly appearing changes of opinion and varying theories are started which compel a review of the subject from another point, showing upon what an uncertain basis our inferences as to psychological processes rest. We prefer to advise the student to ground himself in the terminology and nomenclature of the subject, to study a good text-book on psychology, and hand in hand with this to get the practical experience of an asylum. Only in this way can he have a sound knowledge of a subject which the majority of candidates look upon as a bore, a thing to be got up for a special purpose and afterwards thrown away on the dustheap of distasteful work. If there is to be a separate examination for the final M.D. after a rigorous one in medicine for the M.B. it is, we think, wise of the University of London to insist upon a certain amount of logical and metaphysical training, for there can be no doubt of the great practical value of such subjects in heightening the power of mental analysis, but the examination ought to be of primary importance and scarcely possible of compass by the study of one book such as that we are discussing.

Some of Dr. Hyslop's chapters are admirable, and we may refer especially to the one on Localisation of the Mental Faculties, to that on Evolution, and the chapter on Memory; but in other branches, especially in that of psycho-physics, there is room for improvement. If a candidate could make sure of examination in a certain few indicated directions he could have no better guide. It has been suggested that for this examination definite authors should be named and that the questions should be confined to their works, but where so many different modes of explanation of phenomena are given it is probably wiser to avoid individual theories and to rely upon a wide platform with varying possibilities of superstructure. Viewing this as the intention of the University we can only recommend Dr. Hyslop's book as one of several that will have to be consulted.

Transactions of the Epidemiological Society of London. New Series. Vol. XIV. Session 1894–95. Price 6*s*.

A PORTRAIT of the late Sir George Buchanan, M.D. Lond., LL.D., F.R.S., finds a very appropriate place in the recently issued volume of the Transactions, and the obituary notice which the volume contains was evidently written by one who was familiar with his life and work. Sir George Buchanan's services to the society will be held in grateful remembrance by all the older members. For no less than ten years he acted as its honorary treasurer, and during the years 1881–83 he occupied the presidential chair. The volume of the Transactions which is now before us contains some very valuable papers, and includes Mr. Shirley Murphy's presidential address on the Study of Epidemics, which we had the pleasure of printing in our columns at the time, and to which we also devoted a leading article.[1] There is also in the volume a very interesting paper on Epidemic Disease in the Royal Navy by Fleet-Surgeon T. J. Preston, R.N., the society's secretary for the Navy, which forms an admirable article of reference as to the part epidemic disease has played among the dwellers on our battleships and of the administrative changes which have taken place in the matter of food, the allowance of raw spirit, &c. A *résumé* such as this is will prove of great use to the students of epidemic disease in the Navy.

Dr. Joseph Priestley, now medical officer of health of Lambeth, contributes an article on the Use of Eucalyptus Oil as a Disinfectant in Scarlet Fever, in which he deals in a thoroughly impartial manner with the methods advocated by Mr. Curgenven.

The bacteriological side of the science of epidemiology has not been lost sight of in the Transactions. Dr. Klein's paper on the Relation of Bacteria to their Toxines we have already published in these columns,[2] as also the very lucid and concise article on Immunity by Professor Washbourn.[3] Professor Lane Notter contributes an exhaustive article on the Influence of Soil as a Factor in the Production of Disease especially in Hot Climates. The volume is one

to be included in the libraries of all those interested in the more scientific aspect of epidemiology.

Cottage Hospitals, General, Fever, and Convalescent: Their Progress, Management, and Work in Great Britain and Ireland and the United States of America. With an Alphabetical List of every Cottage Hospital at present opened. Illustrated with nearly 50 Plans, Diagrams, &c., including a Portrait of ALBERT NAPPER, Esq., the Founder of Cottage Hospitals. Third edition. Re-written and much enlarged. By HENRY C. BURDETT, Author of "Hospitals and Asylums of the World," "Burdett's Hospitals and Charities," "Helps in Sickness and to Health," &c. Crown 8vo, cloth, gilt, 10*s.* 6*d.*

THE author of this work is well known to be an authority upon hospital management and finance and to take a deep interest in every subject connected with hospitals. The book now before us, though called a third edition, is practically a new book. Everyone is agreed as to the value of cottage hospitals; indeed, to the hard-worked country practitioner they are an absolute necessity, insomuch as they relieve him from much of the wearing responsibility which forms the chief worry of his life. And the benefit to the patient is no less, for the difference between lying ill and helpless in a not over-clean cottage and bearing the same suffering in a clean airy hospital, looked after by a good nurse, is immeasurable. If there be any, and we hope there are many such, who desire to found a cottage hospital we would refer him to this excellent work. Rules for construction, tables of expenses, hints for avoiding friction in management, appliances and fittings necessary, are all treated in a full and careful manner. The important subject of mortuaries is dealt with, and we are glad to see the necessity of them is insisted on. Even in London some of the parish mortuaries are far from being what they should be. Careful scientific investigation, to say nothing of the reverence due to the dead, is impossible in a dark, dirty, ill-ventilated shed. The book is fully illustrated with architectural plans and diagrams, while the various statistical and other tables will be found very useful.

LIBRARY TABLE.

Scattered Leaves for Working Women. By BESSIE BERNARD. Londonderry: James Montgomery. 1896.—This is an address which was delivered before a working girls' club by the wife of Mr. Walter Bernard, F.R.C.P. Irel., of Londonderry. It is throughout characterised by sound practical common sense as well as by a thorough appreciation of the requirements of those to whom it was addressed, and the publication of it in pamphlet form places some useful suggestions at the disposal of those who seek to improve the condition of the working classes by instructing them in the principles of domestic economy. In the pages dealing with the preparation of food Mrs. Bernard very truly says that a hastily cooked steak is in every way inferior to less expensive parts leisurely stewed with vegetables and farinaceous additions such as barley, macaroni, rice, &c. Much of the information herein contained should be useful to middle-class wives and mothers.

Proceedings of the Philosophical Society of Glasgow, 1894–95. Vol. XXVI. Glasgow: John Smith and Son. 1895. Price 10*s.* 6*d.* — The articles of special medical interest in this volume are on the Antitoxin Treatment of Diphtheria, by Dr. John Glaister, and on the New Rules of the Board of Trade as to Colour Testing, by Dr. Fergus. Professor Ferguson writes on printed editions (some of them quite recent) of the Greek and Arabian chemists; while Lord Kelvin, who was the President of the Royal Society last year, has papers on the Thermal Conductivity of Rocks and the Electrification of the Air.

Early Scoliosis or Curable Curvatures of the Spine. By PERCY G. LEWIS, M.D. Brux., M.R.C.S. London: John Bale and Sons. 1895. Pp. 49.—This little book contains a brief account of the anatomy of the spine, the etiology and pathology of scoliosis, and the diagnosis and treatment. The description of the anatomy is too short and indefinite for those who are unacquainted with the subject and unnecessary for those who have studied anatomy. The treatment is the portion of the subject which is most fully dealt with, and it accords with the view that mechanical restraint cannot strengthen weakened muscles, and that exercises of various kinds are necessary. The book treats only of the milder forms of lateral curvature and may possibly be found useful by those who wish to learn a little more about the treatment than is to be found in the ordinary text-books.

JOURNALS AND REVIEWS.

The *Quarterly Journal of Microscopical Science.* Edited by E. RAY LANKESTER, F.R.S., ADAM SEDGWICK, F.R.S., and W. WELDON, F.R.S. London: J. & A. Churchill. Vol. XXXVIII., Part 4. February, 1896. Price 10*s.*—This part of the *Quarterly Journal* contains: 1. An article by Dr. Bashford Dean of Columbia on the Early Development of Amia calva, a fish that is abundant in the Wisconsin lakes, to which region Dr. Dean betook himself in order to secure the eggs and larvæ in May of last year. This sole survivor of the mesozoic ganoids makes its way in the early spring from the deeper waters to the more shallow and reedy margins of the lakes, where nests are formed, about which the polyandrous female hovers and at length deposits her eggs, which are fecundated as they are emitted and immediately become adhesive, and fixing themselves are watched over by a single male. It appears probable, though this has not been actually seen, that on being hatched they attach themselves to the male and are carried away. The ova are large, oblong, and with well-marked germinal area even at an early period. They possess a well-defined zona radiata and a villous external layer, the villi of which become enormously elongated at the part where the egg is attached. The first cleavage occurs one hour after oviposition. The early gastrula stage is reached in forty-seven hours and the egg hatches in 192 hours. The eggs are meroblastic. Dr. Dean gives an interesting comparative table of the gastrulation of the allied genera of Lepidosteus, Acipenser, and a Teleostean fish. The paper is illustrated by several plates and many figures, and is a valuable addition to our knowledge of the life-history of this, as Dr. Dean terms it, most teleostean ganoid. 2. On Kynotus Cingulatus, by W. B. Benham., D.Sc. Lond. This animal is a new species of worm which has been obtained at Imerina in Madagascar. It is of considerable size, being about nine inches in length, but relatively thin, and is characterised by an extraordinary number of deep secondary annuli, so that from a superficial examination it is impossible to tell which are annuli and which are segments. There appears to be no prostomium. The clitellum is of extraordinary length. There are four pairs of generative pores and a pair of very large "claspers," which present details of structure that Dr. Benham describes at length. 3. Notes on the Ciliation of the Ectoderm of the Amphibian Embryo, by Richard Assheton, M.B., who, as the result of his observations, has been led to suppose that cilia may be with great ease acquired by an organism. The last article is a continuation by Julia B. Platt of her investigations on Ontogenetic Differentiations of the Ectoderm in Necturus, the present section embracing the development of the peripheral nervous system, a very creditable piece of work, but too technical to be abstracted.

The *Sanitary Record.* Vol. XVII. No. 321. Price 3*d.*—In addition to some valuable articles in this volume is

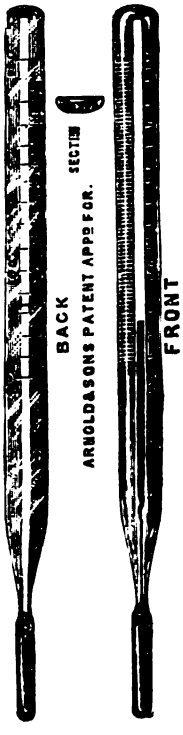
Digitized by Google

a most amusing and not altogether uninstructive paper by Mr. Percy Boulnois on Curious Answers at Sanitary Examinations. We have only space for a few examples, but the whole paper is well worth reading. The definition of a "Common Lodging-house" has puzzled a good many candidates, but we had not previously heard it defined as "a house used by strangers promiscuously for purposes of habitation." Another candidate apparently showed some knowledge of the aërial spread of small-pox when he wrote, "Small-pox is very 'catchy'; I've known cases spread over half-a-mile." A candidate who was questioned as to what precautions he would take during a severe epidemic of small-pox is said to have replied, "I should immediately get an order from the sheriff to seize and destroy the medical officer of health." The following example may be familiar to some of our readers. A death-rate was defined as "a rate which was levied on the living to support the cemeteries."

New Inventions.

IMPROVED CLINICAL THERMOMETER.

OF the making of thermometers there seems to be no end, and it is, perhaps, as well that this is so, for it is an important instrument both in medical and surgical practice.



The special improvement in the thermometer here figured is that all the numbers and graduations are distinctly marked on the back, which presents a flattened surface, thereby rendering the readings more easily and clearly defined, the column of mercury not being in any way obscured or shadowed by the figures and divisions, as is the case in all thermometers where the divisions are marked on the front of the instrument. This is an advantage which will be readily appreciated by the profession in general. Again, both the instrument and the case in which it is placed, having a perfectly flattened surface, it is impossible for either to roll off a table with the consequent possibility of a breakage. These thermometers certainly show a marked improvement over some of the instruments now on the market, and are manufactured by the well-known firm of Messrs. Arnold and Sons of West Smithfield, E.C., from whom they can be obtained.

THE "SPARE HAND."

THE "spare hand" is a very convenient pattern of funnel-holder, consisting of a ring about an inch wide tapering to the usual angle of a funnel and supported on three stout wires rising perpendicularly from a ring-shaped base or foot. This foot is sufficiently heavy to ensure stability and is made of flat bar-iron about ¼ in. wide bent hoopwise into three-quarters of a circle so that it stands on its edges. The funnel is made of ebonite; it is of the usual shape and is not attached permanently to the stand, but fits comfortably into the conical tin-plate ring at the top. The "hands" are of various heights, from 17 in. to 8½ in., the corresponding internal diameters of the annular base being from 7½ in. to 4½ in. In this way a funnel may be conveniently supported over any ordinary bottle, basin, glass, or other receptacle either for the purpose of bottling or filtering liquids or for transferring powders, berries, or small crystals to narrow-necked vessels. The appliance is the contrivance of Mr. A. Haslewood, M.R.C.S. Eng., of Buxton, who originally designed it for dispensing purposes, but it is obviously applicable to a multitude of domestic and trade operations. The London agents are Messrs. Burgoyne, Burbidges and Co., 16, Coleman-street, E.C.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

ELECTION OF PRESIDENT.

AN extraordinary meeting of the Comitia was held on March 30th, being the day following Palm Sunday. In the absence of the President, Sir JOHN RUSSELL REYNOLDS, Sir WILLIAM BROADBENT, as Senior Censor, was in the chair and explained that the President had asked him to express his extreme regret that, owing to indisposition, he was unable to be present, but Sir William Broadbent added that the College would be glad to hear that Sir J. Russell Reynolds was progressing favourably, and had that meeting been held a week or so later in all probability he would have been able to be present.

The Registrar, Dr. LIVEING, then read the President's address. Sir RUSSELL REYNOLDS passed in review the principal events which had happened in the College during the past year, making special mention of the medals and scholarships which had been granted and the various gifts and acquisitions which had been acquired by the College, including Dr. Weber's additional gift of £500 to endow the necessary expenses connected with the Weber Prize. The financial affairs of the College were stated to be satisfactory. The proposed formation of a Teaching University of London was also mentioned, together with a summary of the steps which had been taken to attain that object, and it was hoped that a Bill would be introduced into the Houses of Parliament directly after Easter so that the views of the Legislature might be obtained. Among other important matters dealt with in the address was the petition presented in favour of admitting women to the College examinations. Sir J. Russell Reynolds expressed a strong hope that the Fellows would continue to uphold the old traditions of the College and withhold their consent to such an innovation. In conclusion, he explained that his present state of health compelled him to request the Fellows not to vote for him as President again on that day. He had suffered three times from influenza and the depressing effects of that malady were still upon him.

Dr. POLLOCK proposed a resolution expressing the thanks of the College to the retiring President for his address and hoping that he might shortly completely recover his usual health and strength. This was seconded by Dr. PYE-SMITH and carried with acclamation.

Sir WILLIAM BROADBENT in a few remarks drew attention to the lectures which had been delivered before the College during the past year and announced that the University of Edinburgh were about to confer on Sir J. Russell Reynolds the degree of LL.D.

The election of President was then proceeded with in the usual manner. The first ballot resulted as follows:—Dr. Wilks, 76 votes; Sir William Broadbent, 20; Dr. Dickinson, 9; Dr. Ogle, 9; Sir William Roberts, 7; Dr. Church, 6; Dr. Pollock, 6; Sir William Priestley, 3; Dr. Douglas Powell, Sir Dyce Duckworth, and Dr. Clifford Allbutt, 1 vote each. One voting paper was blank.

As Dr. Wilks did not obtain the necessary majority of two-thirds of the votes, a second ballot was taken between him and Sir William Broadbent, when the numbers were announced to be—Dr. Wilks, 114; Sir William Broadbent, 22. Dr. Wilks was therefore declared as having been elected President, the oath being administered by the Senior Censor.

Dr. WILKS, in a few well-chosen words, thanked the College for the honour they had done him in electing him as President. He had never sought for such a prize, but now that he had won it, although he had already exceeded the years allotted to man, he should devote whatever force remained to him to the service of the College.

The College seal was then set to a lease to the Surveyors' Institution of certain rooms at the Examination Hall.

The following communications addressed to the College were received: (1) from the Royal College of Surgeons of England reporting certain proceedings of the Council on Feb. 13th and March 12th; (2) from the Mayor of Dôle, France; and (3) from Sir James Dick, K.C.B., R.N.

The President then dissolved the Comitia.

THE LANCET.

LONDON: SATURDAY, APRIL 4, 1896.

THE Bill introduced by the Lord Chancellor on March 20th, and read a second time, is a measure which proposes to check the liberty of publication of evidence of indecent matter given in the High Court. As the law at present stands there are two methods by which the publication of indecent matter can be checked, but the limit of action in either case is so restricted that it cannot be doubted that additional powers are desirable. In the first place the court may sit *in camerâ*, but according to the Lord Chancellor this only obtains in the following cases: (1) in lunacy inquiries; (2) in Chancery investigations in the matter of its wards; (3) where the object of the action might be absolutely destroyed by hearing it in public; and (4) in hearing at petty sessions. In the former two the general rule is not broken "because in the ordinary sense the administration of justice is not concerned." It will be seen that the safeguard under consideration is very partially applied, and, moreover, the nature of the exceptions narrated can obviously only touch the fringe of the alleged evil. The other check on the publication of indecent matter divulged in the courts is the Press Act, but this is rarely put in force in the cases under consideration on account of the general terms as to who should prosecute and the expense incidental to litigation. The Bill brought in by the Lord Chancellor proposes to impose on the judges of the High Court the responsibility of ordering what evidence shall not be published, and to inflict punishment on offenders by making them guilty of contempt of court. It will be remembered that a few years since a similar Bill was introduced, but in this those who contravened the order were to be liable to a criminal indictment for misdemeanour. We are not surprised to learn that the Lord Chief Justice, the Master of the Rolls, and the majority of the judges are strongly opposed to adding to offences already within the category of contempt of court. It is impossible not to recognise the extent and weight of this opinion. However, this is a detail and can be remedied in committee.

It is astonishing to find such a wide divergence in the views held on the one hand by the Lord Chancellor, Lord JAMES, and the Marquess of SALISBURY, and on the other by the Lord Chief Justice, Lord HERSCHELL, and Lord ROSEBERY as to the advisability of curtailing the freedom of publication by the press of the evidence given before our tribunals. We feel constrained to subscribe to the arguments of the former speakers that further means are wanting to shield public morality. Can anyone jealous of the purity of English homes contend for one moment that matters obscene and indecent, however guardedly reported, are not almost daily recorded in the newspapers? The very care exercised by the most reputable journals is at once a stimulus to the imagination of the prurient. Youth is the age in which idealisation is exhibited in fulsome glow and strength and in which receptivity is most acute. Given the keynotes of stories abounding with the history of the animal passions and those whom it is specially desired to preserve from contamination will not only readily fill in the blanks but add fancied embellishments to tales already inimical to the maintenance and growth of virtue.

The Bill as it stands confines the power of censorship to the judges of the High Court, and there seems to be almost a unanimity of legal opinion that it would be dangerous to extend it to petty sessional magistrates. The scope of its influence is thus greatly minimised, so much so in fact that it is questionable if the possible evil of abuse of the power would not be more than counterbalanced by the probable gain from its wider distribution.

Thus far we have sketched the general terms of the Bill and the arguments which have been advanced by the Lords for and against its acceptance. There is, however, one question of paramount importance to our profession and that is that no exception is made in favour of the medical journals which are not addressed to the public. To prohibit the publication of evidence which has a direct scientific application in organs the primary and special function of which it is to digest such evidence and furnish products that work for the physical and moral well-being of the community seems to us a short-sighted policy. It will be granted that no section of the press is more careful to exclude obnoxious matter from its reports. Moreover, where it is necessary to discuss questions relating to delicate subjects it is done in highly technical terms so that perusal of the text by the general public is little likely to lead to information harmful to public morals. It is obvious that the medical press must be exempted from the repressive measure we are generally advocating, and some means consequently will have to be devised to decide what are and what are not purely medical journals. The Legislature could not undertake this discrimination, nor could it be left to the discretionary power of the judges. We would suggest that the selection be left to the General Medical Council, and that that body should be asked to supply a schedule containing the names of those publications which it considers to to be strictly "medical journals." The General Medical Council should also be empowered to add to such list the names of new medical publications should occasion arise.

THE Registrar-General's Annual Summary, giving particulars of the deaths registered in London and other large English towns in the year 1895, has just been published. Although issued in the form of a mere pamphlet, this return, as will presently appear, is really of considerable importance. The earlier annual summaries, compiled by Dr. FARR some twenty-five years since, were little more than aggregations of the facts for the respective years which had been already published in the weekly bills of mortality. Since that date the successive annual issues have been gradually improved and the area and population dealt with have been extended. For the reason that these summaries are condensed from the weekly returns

Digitized by Google

of the local Registrars they can be published much earlier in the year than the more elaborate annual reports of the Registrar-General can possibly be completed, because the tabular matter of the latter is classified from the certified copies of the death registers by skilled experts in the statistical branch at Somerset House. For this very reason, however, the latter series of reports are much more trustworthy in point of detail than the former. Nevertheless, for the practical purposes for which they are intended the data contained in the annual summary are perhaps sufficiently precise to furnish useful provisional rates of mortality.

With the improvements and additions which it has received quite recently, the Registrar-General's annual summary will probably be regarded by sanitarians as the most useful of all the statistical publications of Somerset House. It now furnishes, with commendable promptness, carefully tabulated returns of births, deaths, and causes of death, with corresponding birth- and death-rates for each of the 100 chief towns of England and Wales, which, taken together, contain about one-third of the total population of the country. The rates of mortality for these towns, which constitute so many separate sanitary areas, are available for comparison, and having been duly corrected at the central office are almost indispensable to the medical advisers of the local sanitary authorities, both in London and in the provinces, for the preparation of their annual reports. The average mortality last year n the thirty-three great towns of England and Wales was equal to a rate of 20·7 per 1000 of the population, and was, therefore, higher than the extremely low rate of 1894 by 1·1 per 1000. Among these towns the rate ranged from the lowest, 14·5 in Croydon and 19·9 in London to 25·7 in Salford and 28·8 in Liverpool. These are the uncorrected rates; but, as is usefully shown in the summary, if the rates be corrected for age and sex differences of population they will be considerably modified, especially in the larger manufacturing towns, where correction invariably means increase in the mortality. Instead of expressing corrected local mortality in the ordinary way—i.e., as so many deaths in a thousand of population—it is easy by the help of a table here published to express it as follows:—The same number of lives that in the year 1895 gave 1000 deaths in England and Wales, gave 1193 in the thirty-three great towns, and whilst it gave only 806 deaths in Croydon, it gave as many as 1130 in London, 1541 in Salford, and 1707 in Liverpool. Infantile mortality in the great towns corresponded to a rate of 182 per 1000 births, and was higher than that recorded in these towns during any year of the preceding decade. The mortality from diphtheria and diarrhœa showed an increase last year, whilst that from small-pox, measles, scarlet fever, whooping-cough, and fever was below the average. In the metropolis the deaths registered last year were below the average, they corresponded to a rate of 19·8 per 1000, which is reduced to 19·4 per 1000 by excluding the deaths in public institutions of persons known to have been strangers. Of the total deaths in London last year nearly 27 per cent. took place in public institutions. About one in every seven deaths occurred in a workhouse or workhouse infirmary, one in every fifty-three in a metropolitan asylum hospital, one in every eleven in some other hospital, and one in every fifty in a public lunatic or imbecile asylum. Infantile mortality in London, as in the other great towns, was above the average: it was equal to 166 per 1000 births. The rate was lowest in the northern group of sanitary areas and highest in the central group. The net gain in life saved in London during 1895 is represented by 1263 lives; in other words, if the mean death-rate prevailing in the previous decade had continued throughout 1895 not fewer than 1263 lives would have been sacrificed in addition to those actually lost by death.

On the other hand, however, excessive mortality occurred last year from diseases which for many previous years had shown exceptional fatality. There was, for example, an excess under the heads of influenza, diphtheria, and cancer, as compared with the corrected average. Influenza caused not fewer than 2156 deaths in the metropolis in the year 1895, of which as many as 1570 occurred between the middle of February and the end of March. In 12 of the 43 metropolitan sanitary areas the deaths from influenza exceeded the number recorded in any year of the preceding five. Compared with the average in those years, the excess in 1895 was least in the eastern group of areas and greatest, amounting to 65 per cent., in the southern group. Amongst other common zymotic diseases measles and diarrhœa were unusually fatal last year in London, whilst small-pox, scarlet fever, and whooping-cough were less fatal than is usual. The incidence of mortality in the various sanitary areas is seriously affected by the deaths in hospitals and other public institutions. With the object of affording means of comparison between the sanitary districts or groups of districts a table has been inserted in the annual summaries since 1885 in which the deaths at institutions are distributed to the sanitary areas from which the deceased had originally been admitted. A second table is also added in which the deaths from various causes in groups of sanitary districts are reduced to rates per 1000 of the population, and these results are further placed in comparison with the average rates in the previous decade. According to the 1895 tables small-pox does not appear to have been notably prevalent in any group of sanitary districts. Measles was exceptionally fatal in the central and eastern groups, and scarlet fever, diphtheria, and diarrhœa in the eastern group. The corrected death-rate from phthisis, which was given in these summaries for the first time in 1894, still seems to affect exceptionally the central group of districts. In the sixty-seven English towns of secondary importance the death-rate in 1895 was equal to 18·6 per 1000, exceeding by 2·6 the unusually low rate of the previous year; the proportions ranged from 10·1 in Hornsey to 25·7 in Merthyr Tydfil and 26·0 in Longton. Infant mortality averaged 176 in these towns, and ranged from 121 in Hastings to 240 in Longton. The mortality from the principal zymotic diseases averaged a rate of 2·40 per 1000, and ranged from 0·62 in Bath to 4·79 in Warrington and 5·85 in Barnsley. From returns submitted by the authorities of thirty-nine of the principal foreign and colonial cities, with an aggregate population of 23,500,000, it appears that the mean death-rate last year was equal to 23·6 per 1000 of the population. As had been the case in previous years, the rate last year varied

Digitized by Google

enormously in those cities; for whilst it did not exceed 13 per 1000 in Sydney and 14 in Brisbane, it was as high as 36 in Moscow, 38 in Madras, and 48 in Cairo.

THE choice of a man to fill the post which qualifies its holder for official recognition as the head of our profession in this country can never be without great interest to us all, but the result of the recent election to the Presidential chair of the Royal College of Physicians of London had been so universally forecast that the excitement to be derived from suspense or from rival appraisement of different claims did not enhance that interest. From the moment it was known to be Sir J. RUSSELL REYNOLDS'S intention to request his colleagues not to re-elect him to the chair which his dignity and courtesy have so well graced for the past two years, the eyes of the profession were turned upon the distinguished physician who was marked out by the place that he occupied in the poll of 1893 as an urgent claimant for the reversion of the honours. Sir J. RUSSELL REYNOLDS obtained the presidency in 1893 by the narrow majority of three votes over Dr. SAMUEL WILKS—the opinion of the profession being very clearly registered that between them there was not much to choose—and when the regretted information that the former would retire became known to the profession it was widely felt that upon the latter the new choice would fall. The claims of Dr. WILKS to such recognition from his fellow physicians are, indeed, of high order. Through a long and honourable career he has invariably upheld the highest and purest standard of professional morality and ethics; he is esteemed far beyond the great medical school with which his name is linked; his contributions to pathological science are recognised all the world over; while his connexion with the University of London may be of no small advantage to the College in any further proceedings for the reconstitution of that University. On many grounds Dr. WILKS has well earned the right to the "blue riband" of the profession, while his election will be well received by the profession at large for it is men of his stamp whom it is a delight to honour. We wrote of Dr. WILKS in almost these identical words after the result of the election of 1893 had been announced, and in repeating them we beg to congratulate him upon the official stamp that was set last Monday upon the sentiments therein contained. We have also to offer a few words of cordial adieu to the retiring President, for whose tenure of office no one has anything but words of warm praise. The deliberations over which he has presided have taken from him a quiet and business-like tone that has greatly facilitated official labour; he has not spared himself, but for others the wheels have always run smoothly. We note with great pleasure that Sir WILLIAM BROADBENT, the Senior Censor of the College, was asked to state to the last Comitia that Sir J. RUSSELL REYNOLDS'S state of health has much improved and was still improving. The profession knows well what the terrible prostration of recurrent attacks of influenza means and will join us in heartly congratulating Sir J. RUSSELL REYNOLDS on his recovery therefrom and in wishing for him many full years wherein to devote the freedom from official toils that he has felt it right to seek to the welfare of the sick and the advancement of medical knowledge.

Annotations.

"Ne quid nimis."

KITSON v. PLAYFAIR.

THE trial of the above cause, before Mr. Justice Hawkins in the Queen's Bench Division of the High Court, was brought to a conclusion on Friday, March 27th, when the special jury returned a verdict for the plaintiff, the damages being assessed at £12,000. Leave has been given to appeal, and consequently we are precluded from discussing at the present juncture the merits of this remarkable case. We will, therefore, content ourselves with a short historical *résumé* of the facts. Mrs. Kitson—one of the plaintiffs—after some years' residence in Australia came to this country, her husband staying abroad. Some sixteen months subsequently to her arrival in England she had occasion to consult Dr. R. M. Williams for metrorrhagia. With Mrs. Kitson's consent Dr. Playfair was called in. A month later, as the hæmorrhage had not ceased, it was decided to make a further examination under an anæsthetic. On this occasion a substance was removed from the uterus which, in Dr. Playfair's opinion, was the result of a recent pregnancy. He informed Mrs. Kitson of the conclusion he had formed. It may be remarked parenthetically that Mrs. Playfair was a sister of Mrs. Kitson's husband and also of Sir James Kitson. The latter gentleman, in conjunction with another brother, had up to this period made Mrs. Kitson a yearly allowance. The gist of a lengthened correspondence between Dr. Playfair and Mrs. Kitson had regard to the termination of social and family relations between their respective families unless Mrs. Kitson could give Dr. Playfair a satisfactory explanation of her recent condition. In the end Dr. Playfair confided his conclusions to Mrs. Playfair and also to Sir J. Kitson. Mrs. Kitson and her husband brought an action for slander against Dr. and Mrs. Playfair. The pleas put on the record by the defendants were two: (1) that they had not published the slander; and (2) that the communication made to Sir J. Kitson was privileged. No plea of justification was entered and consequently the judge would not allow the merits of the case as bearing on the duration of the pregnancy to be gone into, or, in other words, he ruled that it was not competent for Dr. Playfair to attempt to prove the truth of the conclusions he had formed. From a medical point of view the case is one of surpassing interest, whether we consider its bearing on the question of retained products of conception or its graver reference to professional etiquette. Concerning this latter phase we take occasion to recognise the generally gratifying tone of the organs of public opinion in their comments on the discharge by the great body of the medical profession of the delicate duties incidental to its vocation. The agreed terms upon which the appeal should be made to the higher court were not disclosed by counsel. It is open to contend (1) that the communication made by Dr. Playfair to Sir J. Kitson was privileged; (2) that there was misdirection by the judge who tried the case; (3) that the verdict was against the weight of evidence; and (4) that the damages were excessive. There is no need, however, to anticipate the course of procedure. When the litigation has terminated it will be our duty to offer a general criticism of the case in so far as it affects the interests of our profession and of the public.

THE ILL-REGULATED SALE OF POISONS.

IN THE LANCET of March 28th we directed attention to the case of a child who died suddenly from the effects of a

Digitized by Google

home-made concoction of laudanum administered as a cough mixture. Our excuse for again alluding to it is not that such accidents — if so they should be described — are very uncommon. Most practitioners have unfortunately had experience of them. To us the circumstances of the case referred to are suggestive of other defects than mere parental indiscretion. The very fact that an opiate should be readily obtainable by any casual purchaser is an anomaly which assuredly cannot tend to strengthen belief in the adequacy of the Sale of Poisons Act. It is true that laudanum is saleable only under certain restrictions, and in particular that it must be labeled "poison." But, on the other hand, there is practically no limitation as to the amount that may be purchased. The unaided discretion of a trained dispenser and the poison label sum up the total of restrictions in the case of opiates. A number of drugs little, if at all, less potent are as easily obtainable. Many more, the strong acids and alkalis among them, are freely obtainable without mark or sign, even without the guarantee of a duly qualified salesman. It has been contended that in the case of these latter some freedom should be permitted when the article sold is required for ordinary use in the household, in the arts, or in agriculture, and there is some force in the contention. Yet when we examine the matter more closely the objection does not seem to be insuperable. There need be nothing to prevent a purchaser from obtaining whatever drugs of this class he requires under suitable precautions at the nearest druggist's, or in rural districts from the holder of a special licence. Undoubtedly some skill will be required in the adaptation of practice to theory before we can hope to come at a final settlement of this question, and perhaps an absolute settlement may not be practicable. Nevertheless, it is clear, in the light of such unfortunate occurrences as that we have mentioned, that much more strenuous efforts are called for than have yet been made to adapt the machinery of the law to its professed purpose of regulating the sale of poisons. Any legislative effort, moreover, must, of course, take account as heretofore, but with even more particular care, not only of single drugs, but of the same in their combinations. The effect of a preparation does not depend on any pharmacopœial expression. An irritant or narcotic nostrum, however tastefully prepared, may be as truly a poison as any accredited compound of strychnia or aconite, and this is a point which ought to be more clearly recognised in practice than it is.

THE LABOUR COLONY SYSTEM.

THE last volume of the *Proceedings of the Philosophical Society of Glasgow* contains a carefully reasoned and suggestive article by Professor R. Patrick Wright pleading for the institution of "farm colonies" as a means of solving the difficult problems connected with the unemployed. Under the Scotch Poor Law it is illegal for relief from the rates to be given to able-bodied persons, and even though parochial authorities may interpret the statute with some leniency it is unquestionable that no organisation exists for the assistance even of the industrious poor who may be, through no fault of their own, suddenly thrown out of work and brought to the verge of starvation. Professor Wright argues that the labour colony system can deal humanely and effectually, not only with these cases, but also with discharged prisoners, habitual idlers, and confirmed vagrants. In Germany there are twenty-six such colonies, and in England the Salvation Army has one at Hadleigh in Essex. Turning to the financial side of the question, he mentions that during seventy-four days in the winter of 1892–93 the Glasgow magistrates provided work for the unemployed in stone-breaking, trenching, and digging, subsistence wages only being paid. The whole cost incurred was £3103, and the value of the work done was estimated at £1402, so that the municipality incurred a loss of £1701. As the average number of men at work was 467 the outlay per man per annum, calculated on this deficit, was £17 19*s.*, or one-third more than the average cost per head on the farm colonies, without any of their incentives to industry and thrift. It is satisfactory to learn that a philanthropic association in Glasgow may, perhaps, put some of these doctrines to the test of actual practice during the present year.

ROENTGEN RAYS AT THE CLINICAL SOCIETY OF LONDON.

PROFESSOR SILVANUS THOMPSON gave a demonstration before a special meeting of the Clinical Society of London on March 30th of the method of production and the practical use of the Roentgen Rays. He exhibited the gradual changes which the character of the electrical current undergoes as the air is exhausted within a tube and demonstrated the differences between the kathode and the "x" rays. He stated that in producing the photographs he had found the ordinary dry plates to be quite as good as the extra rapid ones, and he also dwelt on the advantages of a screen coated with platinocyanide of potassium when using the cryptoscope. He added that he believed a great development in the photographs would shortly take place in the direction of the recognition of the relative depth from the surface of the various shadows in the picture by taking photographs of objects at two different angles and then mounting them in a binocular stereoscopic apparatus. The demonstration was attended by nearly 400 of the members, and the hearty applause at its close showed how keen had been their interest and how great their appreciation of the efforts of the lecturer.

TUBERCLE AFFECTING THE EYE.

IN the *Archiv für Augenheilkunde*, Band xxxi., Heft 4, p. 359, Dr. Rudolf Denig publishes the results of investigations which he has made in order to ascertain the frequency of primary tubercle of the eye and the number of cases in which it occurs in patients suffering from tuberculous affections of other organs. In order to carry out his purpose Dr. Denig went carefully through the literature of recorded cases and also examined 200 patients suffering from tuberculosis of the lungs, bones, or lymph glands. His results are as follows. Out of 72 cases of tubercle of the conjunctiva, in 52 no other deposits of tubercle could be detected in any organs of the body; in 14 the signs of further disease were indefinite; in 7 only of the cases was there undoubted tuberculous disease in other organs; and in 3 there were evidences of old tuberculous trouble. Out of 86 cases of tubercle of the iris and ciliary body, in 67 no further deposits could be found at the time of examination; 27 of these, however, were anæmic, emaciated patients in whom tuberculous trouble was suspected but could not be definitely detected; the other 40 were perfectly healthy except for the eye trouble; in 4 cases there were signs of old disease. Out of 31 cases of tubercle of the choroid, in 16 no other evidences of tuberculous trouble could be established. Of the 200 patients suffering from tuberculosis whom Dr. Denig himself examined, in only 5 did he find the disease affecting the eye. He therefore came to the conclusion that as local tuberculous disease of the lungs and bones are fully recognised, so we must accept local tuberculous disease of the eye in the sense of that organ being primarily affected. Another form of tubercle of the eye, which he maintains is much rarer, is a metastatic deposit from some other deposit, either in the lungs or elsewhere.

Digitized by Google

With regard to prognosis, he bases this upon the form which presents itself. If the disease is primarily in the eye the prognosis is generally favourable, but care must be taken to distinguish between the appearance of granulations and the irregular form which has been described by Leber as "abgeschwächte Tuberkulose." The existence of granulations points to a metastatic deposit and the prognosis is then unfavourable.

THE REMUNERATION OF POOR-LAW MEDICAL OFFICERS.

"A COUNTRY PARISH DOCTOR," whose letter was published in our issue of last week, has our entire sympathy in the disadvantageous position in which he finds himself by reason of his inadequate remuneration, his age in relation to superannuation, and the questionable return which is to be made to him as a result of his further reduced salary should the Poor-law Officers' Superannuation Bill become law. We have long felt that the medical profession is degraded by the paltry pittances doled out to its members who have taken Poor-law appointments in many districts. A superannuation allowance in prospect is not a great inducement to a medical man if the salary on which it is to be based, and that too after certain deductions have been made annually, is of the miserable amount which pertains to only too many such appointments. It will doubtless always happen, moreover, that a measure designed to benefit the many, as in the case of this Bill, will work harshly as regards a few, and while there are certain to be others in the position of our correspondent it is a subject for serious consideration whether the present Bill should be imperilled by striving to amend its provisions so as to meet individual needs. One point, however, we should like to see altered—namely, the age at which superannuation may be claimed. We certainly think that officers should be entitled to retire on a pension at the age of sixty years if they be so minded. And this would, we imagine, remove one cause of our correspondent's complaint.

THE PLAGUE IN HONG-KONG IN 1894: A STORY OF CHINESE ANTIPATHIES.

THE annual report of Sir William Robinson, the governor of Hong-Kong, for 1894 to the Colonial Office is one of much interest, by reason particularly of its references to the plague which that year attacked the settlement. It was early in April that the plague was heard of in Hong-Kong as raging on the mainland near Canton, and not for some little time did the island become affected. But in the middle of May Hong-Kong was itself invaded by the dread disease, and that, too, at a season when, by reason of drought and a rising temperature, the malady was not long in severely attacking the native population. The cases gradually rose from 20 to 30 per diem, and then to from 60 to 70 daily, and even to upwards of 90, and on one day to 109, inclusive of dead bodies picked up in the streets. The report speaks of the discovery of the plague bacillus and directs attention to the strange and unfortunate antipathies which the natives manifested towards the European medical staff in their efforts to curtail the spread of the epidemic. The hospital hulk *Hygeia* was moored near the shore, and every care was taken to make it replete with conveniences and staff for the proper treatment of the sick. Sir William Robinson says, however, that—

"From the first the Chinese strongly objected to the removal of their sick to hospitals under European management. Educated to insanitary habits, and accustomed from infancy to herd together, they were unable to grasp the necessity of segregation; they were quite content to die like sheep, spreading disease around them, so long as they were left undisturbed, and they preferred to see their sick friends and relations suffering unspeakable miseries rather than be parties to their removal to European hospitals, where every comfort was provided. These feelings, no doubt the result of blind prejudice and superstition, naturally prompted concealment, which eventually necessitated the organisation of search parties and a system of house-to-house visitation."

Harrowing tales were told of the devices to which the natives resorted to try to conceal their sick from the search parties sent out day by day. This action on the part of the natives made any speedy curtailment of the infectious malady the more difficult, and, indeed, in great degree rendered the efforts of the cleansing and disinfecting volunteer staff nugatory. The epidemic caused 2550 deaths before it ceased in early September, and the necessity of burying the dead in common graves was a great shock to the feelings of the people, whose chief form of religion consists in the rites and ceremonies of burial and in the annual worship of their dead. The feelings thus roused led the people to open rebellion, and concessions, such as the presence of Chinese medical attendants in the European hospital and the removal of those patients who were fit for the journey to Canton, had to be granted. The demand was made that plague-stricken people should be allowed to leave the colony of their own free will. This preposterous demand being refused the people left the settlement to the number of 100,000 of all ranks. Of the patients only 18 per cent. of those of Eastern extraction recovered, whilst 82 per cent. of the cases among European residents ended in recovery, a result sufficiently and indeed strikingly indicative of the difference of treatment accepted by the two classes. Trade was deplorably interfered with, and just as hopes of better things were anticipated on the subsidence of the plague the bursting out of the war storm once again rendered matters terribly unsettled. But taking the year throughout the trade of the colony showed a very creditable aggregate so far as the mainland ports were concerned.

EPILEPTIC MELANCHOLIA.

DR. J. M. FINKER, assistant superintendent of Rockwood Hospital, Kingston, Ontario, reports an interesting case of epileptic melancholia[1] in which after death foreign bodies were found in the heart and lung. The patient was a labourer's wife aged thirty-two. She had had several attacks of insanity for four years previous to her admission to the asylum. Her mother and grandmother were insane; the latter was also subject to epileptic seizures. The patient had made several attempts on her own life, on one of these occasions opening two large veins in her arm with a piece of broken bottle and a pair of scissors. When she was under the suicidal impulse she used to say that "she would be better out of this world, that no one cared for her." At times she was fairly well and occupied herself in sewing or knitting. Whilst in the asylum her whole history was one of suicidal attempts which were shown by the scars on her arms and forearms. Trephining was performed, a portion of the brain convolution being removed corresponding to the nervous supply of part of the local origin of convulsions. She made an excellent recovery from the operation. She was greatly relieved of her distressing mental symptoms, but pulmonary tuberculosis supervened and ran a rapid and fatal course. At the necropsy the heart was found to weigh nine ounces, and on examining the left auricle something sharp was felt near its appendix, which proved to be a needle. On exposing this it was found embedded in the wall of the left ventricle, close to the anterior interventricular groove. The needle pointed upwards, leaving the left ventricular wall just anterior to the aortic valve. Then it penetrated the

[1] Canadian Practitioner, February, 1896.

Digitized by Google

wall of the left auricle at the margin of the appendix auriculæ. The pointed portion of the needle then extended across the opening into the appendix. The point was just touching the opposite wall of the auricle, where a little papilla of vegetations was set up by the irritation of the point of the needle. In the ventricle the needle penetrated the heart muscle immediately behind the coronary artery on its way to the anterior interventricular groove. The needle was firmly embedded in the tissue, so that it could not be pulled out without using considerable force. It was one and five-eighths of an inch long. It was black in colour and its surface quite smooth. The left pleura was firmly adherent throughout. The superior lobe of the left lung was a mass of tuberculous nodules and some small cavities. The inferior lobe presented another feature of interest in the presence of a broken knitting needle. There was an old cicatrix in the skin to the left margin of the sternum. The needle, pointing downwards, entered the lung at the anterior border of the inferior lobe about two inches from the lower margin, passing downwards, backwards, and slightly outwards, reaching the outer surface of the lung at a point about four inches from its posterior border and two inches above the circumference of the base. The needle was four and five-eighths of an inch long, the broken end being slightly bent and the other end pointed and sharp. The needle was completely encysted. Neither point emerged before the manipulation of the lung in its removal. It was quite black and was not in any way corroded.

THE QUESTION OF MEDICAL DEFENCE.

THE points raised in Dr. Drage's letter on our article[1] on the report of the Medical Defence Union are well worthy of the attention of the profession. All the same, we entirely dissent from his conclusions. We have consistently discouraged the multiplicity of societies having the same object, and so have advocated the union of the two protection societies. But we fail to see that one good strong society for the one purpose of defence of members of the profession against unreasonable or malicious charges is too much for the work. It is very doubtful, indeed, whether the British Medical Association would add to its strength by attempting the work done now so well by the Medical Defence Union and its sister society. It certainly could not do the defence work better than it is done. And if this work came to be added to the work of the Association, already multifarious enough, the chances are it would be worse done. The disposition of one big body to absorb and appropriate the function of other bodies less than itself, but not less efficient, has many illustrations, and is not to be encouraged. Still more doubtful would be the policy of relieving the corporations from their ethical functions by one huge corporation representative of the whole profession. The bodies that give diplomas cannot be relieved of the disciplinary duties attaching to their authority. The association of such duties with that of examining and admitting to the profession is as old as the oldest qualifying body, and no conceivable Parliament is likely to alter the fact. We entirely agree with Dr. Drage that such bodies should recognise the corporate rights of their members without delay, and that they would strengthen themselves by doing so. But if the British Medical Association is not likely to have handed over to it as a voluntary association the ethical powers of the corporations it has enormous powers as a voluntary association. And it is only fair to say that it has no more used its full powers as a voluntary association than the corporations have used their full legal powers to repress the evils of the profession. There can be no doubt that if ten years ago the British Medical Association had resolved that no one should enjoy its membership who took office in a medical aid association, or any other association which was proved to employ touters and to sweat its medical officers, it would have done much to prevent the evils which are now so seriously degrading the profession? The Association has powers as a voluntary association which it could not have acting under the sanction of Parliament, and it will best serve the profession by retaining its freedom and using those powers well.

[1] THE LANCET, March 21st, 1896, p. 794.

THE VACANCY ON THE SENATE OF THE UNIVERSITY OF LONDON.

SIR JOSEPH LISTER, B.A., M.B., has consented to be put in nomination as a candidate to fill the vacancy on the Senate of the University of London caused by the resignation of Mr. Hutton. Mr. Walter Rivington, B.A., M.B., M.S., has also been invited to become a candidate for the vacant seat. The vacancy is filled by the Crown from a list of three persons submitted by Convocation, and on the present occasion the choice falls on a graduate in medicine or science.

THE PORTSMOUTH CORONER ON DANGEROUS LAMPS.

AT an inquest at Portsmouth on March 23rd Mr. T. A. Bramsdon, the borough coroner, had something to say about cheap lamps. A woman aged fifty had been left in bed with a lamp which two years ago had been bought for one penny. She was afterwards found terribly burned—indeed, in flames—but gave no intelligible explanation of the occurrence. Mr. Bramsdon in his summing up said such lamps were as dangerous as it was possible to conceive and could be termed nothing else but death-traps. Cheap lamps were deplorable, awful things, and their seriousness could hardly be realised. He referred to the continual reports of deaths occurring from the use of such articles all over England and expressed his opinion that the sooner legislation put a stop to their use the better it would be.

THE LATE GIUSEPPE FIORELLI.

MEDICINE owes a debt of gratitude to the distinguished archæologist above named, for he it was who not only enriched the treasure-trove of ancient surgical instruments, but also preserved for the comparative anatomist a vast number of skeletons eighteen centuries old which otherwise would have been lost to history and science. These services he rendered in his capacity of superintendent of the excavations at Pompeii. For twelve years he was the life and soul of the operations by which that buried city has been restored to something like its former self in outline and in detail. Before 1860, the year in which the Bourbon Government was replaced in the Two Sicilies by that of the House of Savoy, excavation was conducted at Pompeii on unscientific lines, more attention being given to whatever objects of artistic or negotiable value could be unearthed than to the determination of the plan of the city, its buildings public and private, its occupations, its *vie intime*. Every visitor to the National Museum of Naples must have profited by the richly represented and beautifully arranged relics of Campanian life placed *en évidence* before him, and supplementing so fully and so vividly a walk through the silent streets and tenantless houses of the once animated "Rome-super-Mare"—the "gay and guilty Brighton of the first century." All that memorable experience was made possible for him between the years 1860 and 1872 by Fiorelli—an epoch in archæology which has been continued under the inspiration of its directing mind to the present day. During those twelve years some 600 skeletons and fragments of human bodies were excavated, all the individuals to whom these skeletons belonged having, with one exception, died in great agony. Suffocated by the dense

Digitized by Google

showers of dust which descended from Vesuvius and which by the heavy rainfall that ensued became so much liquid mud, their bodies were covered by this last as by an envelope, which, on hardening, became "a closely fitting mould" stereotyping every feature of the dead. Gradually the soft parts disappeared while the bones remained within the mould; and so "when the hollows were come upon by the excavators the happy idea occurred to Professor Fiorelli to pour in some liquid plaster of Paris and allow it to harden." The mud, perfectly dry, was with the utmost care peeled from the plaster and in this way a perfect cast was obtained—in the language of Mr. Neville Rolfe, H.B.M. Consul at Naples, "a cast consisting of the bones of the deceased Roman citizen, clad no longer in flesh, but in plaster of Paris, which had assumed the exact shape, not only of his face and body, but of every fold of his clothes." A precious addition has thus been made to the resources of what may be called "historical osteology," and interesting comparisons have been instituted between the bony framework of the Italian as he existed eighteen centuries ago and the Italian of the present generation. These "confronti" strengthen the conclusion come to by Professor Mosso of Turin, who, having found a number of skeletons in a sub-Alpine cave and proved them by accessory evidence to have been those of Roman soldiers of the late Republic, compared them with the skeletons of Italian soldiers recently dead, and placed it beyond doubt that the difference between the two types of men was small and not to the advantage of the more ancient. So that Julius Cæsar's famous Tenth Legion, that could go everywhere and do anything, owed its success as much to consummate discipline and generalship as to any exceptional advantages of physical development. Professor Fiorelli died on Jan. 29th at Naples in his seventy-third year, but for the last decade of his life, with failing eyesight which latterly ended in total blindness, was content to rest on the laurels he had so honourably won.

THROMBOSIS IN CEREBRAL SINUSES.

IN the third volume of the *Edinburgh Hospital Reports* Dr. George A. Gibson and Dr. Purves Stewart report a case of somewhat unusual character and of more than usual interest. The patient was a young woman aged twenty-five years, who was admitted to hospital in a state of unconsciousness. She was said to have suffered from indigestion for a long time and from occipital headache for a fortnight. Four days before admission the headache became much more severe and she began to have attacks of vomiting. She became more and more dazed and stupid and finally unconscious. The family history revealed nothing of significance except that her father had died two years previously from "inflammation of the brain." The patient on admission was found to be well nourished and well developed. The temperature was 102° F. and the pulse and respiration were rapid. She lay on her back, with flushed face, occasionally grinding her teeth, and tossing her limbs in an aimless, restless, uneasy fashion. It was impossible to rouse her. The eyes were almost closed, the pupils semi-contracted but reacting to light, and the appearances of the optic discs and fundi were normal. There was no albumin in the urine, of which a specimen was obtained by means of the catheter. During the night there were recurrent convulsions characterised by extension of the arms and legs, clenching of the teeth, and distinct opisthotonos. The breathing during the fits became loud and stertorous, the face flushed, the pupils contracted, and the eyes directed downwards and to the left. There was no material change in the condition until about 10.30 the next morning, when the respiration suddenly stopped and the patient became deeply cyanosed. Bleeding and artificial respiration brought about distinct but only temporary improvement, but the artificial respiration had to be kept up, and the patient gradually sank and died about three and a half hours after the natural respiration had ceased. At the necropsy the inner surface of the dura mater was everywhere considerably injected and the superior longitudinal sinus and the lateral sinus were occupied by a mixed blood-clot, chiefly dark red in colour, with a slight admixture of scattered white flakes. The convolutions were flattened and the surface of the brain was dry and sticky. The arteries at the base were healthy and free from thrombi. No tubercles were described. There was no morbid condition of the cranial bones. On section the grey matter appeared fairly healthy and so did the white, but the puncta cruenta were unusually distinct. On exposing the lateral ventricles each choroid plexus was found to be occupied by a thrombus, which also occupied the veins of Galen and extended into the straight sinus. The basal ganglia also were found to be extensively altered, being to a great extent replaced by a tissue of dark brownish red colour and of soft and friable consistence. Subsequent microscopic examination showed this to be a result of hæmorrhagic infiltration, doubtless secondary to the thrombosis, especially of the veins of Galen. The internal capsules were unaltered. The other organs showed little change and none of any significance except that in the medulla, among the cells of the right vagus nucleus, there was a small hæmorrhage the result of a ruptured vessel, and this lesion the writers connect, reasonably enough, with the cessation of respiration some hours before death. The case is, as we have said, both interesting and important, and on account of the completeness of the examinations, both clinical and pathological, and the admirable manner in which it is reported it forms a valuable contribution to our knowledge of an obscure and probably not very common form of disease.

SANITARY BURIAL.

AT a meeting of the Church Burial, Funeral, and Mourning Reform Association, held last week at the Chapter House, St. Paul's-churchyard, the Archdeacon of London in the chair, papers were contributed by Sir F. Seymour Haden and Dr. Poore on the Earth-to-Earth mode of burial. The former stated that for the last ten years he had been burying animals, large and small, in the park attached to his house. By digging them up and examining them at intervals varying from one to five years he found that buried at the depth of four and a half feet—the depth required by the Government for the burial of human bodies—an interval of from three to four years was necessary for complete resolution; buried at the depth of one foot a year and a half had proved sufficient for the larger and a year or less for the smaller animals. On the other hand, a body not buried at all, but simply laid upon the ground with a covering of earth a foot thick over it, had completely disappeared (the bones excepted) in a year, the mound of covering earth, which had been sufficient to prevent all smell, retaining its shape, but when it was pressed with the foot proving to be hollow. The body had thus returned to the atmosphere in the shape of oxygen, hydrogen, carbon, and other perfectly harmless products necessary for the nourishment and growth of plants. He (Sir F. Seymour Haden) was amazed at the folly, not to say impiety, of any attempt to beat this provision of nature. Dr. Poore in his paper contended that if a body were buried in such a manner as to further in every way its complete dissolution the land would be ready after due interval of time to receive a second body, and that if the cemetery were systematically and sufficiently planted the earth would be purified and the air around freshened by the green leaves of a flourishing vegetation. The power which scientific burial gave of using the same ground repeatedly after due intervals of about ten years abolished the fear which had

Digitized by Google

been expressed with regard to the amount of ground allotted for burial purposes. An acre of land would prove an ample area for a burial ground in perpetuity for a population of ten thousand persons. Such a burial ground would prove a decided benefit to the living, as supplying in the midst of human habitations a breathing place which is so essential to the general well-being. It was resolved, upon the motion of General Lowry, seconded by the Rev. Septimus Buss, B.D., to ask the Government to formulate into a Bill the recommendations of the Committee of Inquiry on Death Certification appointed by the late Home Secretary at the request of this association; also to ask the Government to institute an inquiry into the effect upon the air above, the earth around, and the water below, of earth-to-earth burial, and other modes of interment.

FLOATING SANATORIA FOR TUBERCULOUS PATIENTS.

IT is some years since M. O. Motschoutkovsky first advocated the provision of floating sanatoria for people threatened with tuberculous disease or suffering from incipient forms thereof, but quite lately he has returned to the subject with renewed enthusiasm. In the opinion of this zealous hygienist the scheme he has theoretically organised down to the minutest detail is certain sooner or later to prove a triumphant success. According to his plan the isolation of a dangerous class can be effectively carried out with the least possible amount of discomfort to its members; and he likewise maintains that by a judicious timing of moves it will be easy to afford the sufferers an excellent chance of recovery under the very best and most favourable climatic conditions. The various anchorages on the list have one and all their special seasons when the meteorological conditions are all that can be desired, and inasmuch as these seasons by no means correspond with each other chronologically it will be practicable for a speedy vessel to transport her passengers from one to the other and thus enable them, as it were, to skim the cream of the collection. As soon as there is any likelihood of a change of weather at any given place the order will be given to go to whatever spot has been proved by experience to be the most appropriate at that particular time of the year. It goes without saying that the ships destined for this service should be specially constructed in accordance with all the most approved rules. For eight or nine months in each year they might be in constant employment, but during three months at least out of the twelve they should go into dock in order to be thoroughly cleansed and disinfected. M. Motschoutkovsky is quite convinced that no stationary hotel or sanatorium in the world could possibly surpass his floating palaces in either comfort or salubrity; while as regards constant variety and change of scene there can of course be no comparison. All that is required is a company with the necessary amount of capital, and at last there seems to be a prospect that such may be forthcoming. That well-known ship-owning association the Austrian Lloyds has placed an order for the construction of a large steamer which is to be specially adapted and fitted for the accommodation of invalids in need of fresh air and a favourable climate. The anchorages that so far have been selected are at Corfu, Alexandria, Palermo, Messina, Naples, Tunis, and Malta.

DEATH CAUSED BY BROMIDE OF POTASSIUM.

THE coroner for mid-Essex held an inquest on March 26th on the body of a man whose death appears to have been due to excessive indulgence in what is usually considered to be a comparatively safe drug—namely, bromide of potassium. Suffering from neuralgia, he had been in the habit of taking this salt in doses of from two to three drachms. The drug does not appear to have produced any of the usual symptoms of bromism, but may have caused the palpitation of the heart of which the deceased had frequently complained. During the night of March 23rd he felt very cold, gave two deep gasps, and almost immediately expired. The medical practitioner who was sent for stated at the inquest that he found the deceased quite dead, his mouth wide open, the eyes half closed, and the pupils somewhat dilated. A bottle containing the drug was on the table and examination showed that it was pure bromide of potassium. The witness attributed death to failure of the heart's action caused by taking the bromide. This case is interesting for several reasons. It proves in a marked manner the danger of taking any drug, however harmless it may be reputed to be, in large and repeated doses without the advice of a medical man. No doubt in this instance a medical attendant would have recognised the depressant action the salt was exerting upon the heart and would have discontinued its use. Even in the most modern works on therapeutics this danger is not mentioned, yet it is well known that all potassium salts cause "depression, shown by diminished energy of contraction of the cardiac muscle, with final stoppage in diastole" (T. Lauder Brunton). As this bromide is constantly administered in large and repeated doses the action of its basic constituent should always be borne in mind, and if signs of its depressant effect are observed its use should be abandoned, the bromide of some other base being selected if in other respects the action is beneficial. Many secret remedies for "fits" contain this drug in large quantities and it is evidently desirable that the public should be warned that their use is not unattended with danger.

SÆVÆ NOVERCÆ.

THE traditional stepmother has not apparently become quite extinct as a species if one may judge from two horrible cases reported this week from Hastings and Epsom respectively. At an inquest at the seaside town on an infant named Batt two witnesses alleged that the deceased's stepmother had said she wished "the little —— was dead," and a third said she saw her throw it up in the air and catch it with the remark, "Die, you little ——, and I will have your insurance money," a paltry forty or fifty shillings. The coroner said he had never seen a child with so many bruises, and the jury in the absence of direct evidence returned an open verdict, death having been the result of an injury to the head. They added their opinion that the woman's conduct had been inhuman and cruel and such as demanded some punishment which it was not in their power to give. The termination of the other case was a great deal more satisfactory. A woman named Mary Frost was charged, at the instance of the National Society for the Prevention of Cruelty to Children, with cruelty to her two step-children—a boy and girl of eight and nine years respectively. They were beaten severely with a stick while in bed, and after their father had gone to work, for "stealing" sugar. Then the woman put a poker in the fire, and when the poor children came down to breakfast they were made to stand up and put out their tongues. The woman then put the red-hot poker so close that the children put up their hands to save themselves and were severely burned. The woman pleaded that this was a recipe of her own to cure lying. This reads so unpleasantly that it is a relief to turn to the remarks of the chairman. He characterised the punishment as excessive and the threats as atrocious. A fine the magistrates considered would be no punishment, for her husband would pay it; the woman would have to go to prison for a month. Stepmothers, he added, must be taught to treat children properly.

INTRADURAL PUNCTURE OF THE SPINAL CORD.

IN a recent number of the *New York Medical Journal* Dr. Killiani records a case of some interest. A patient, forty-five years of age, fell on his back from a height of twenty feet. On admission to hospital an hour later he was still suffering from shock, and there was complete paralysis of both lower extremities and of the rectum and bladder. The anæsthesia reached to an imaginary line drawn through the third lumbar vertebra and a point about two centimetres below the umbilicus. There was a spot of extreme tenderness at the bend of the third lumbar vertebra, but no deformity or crepitus. There was slight ecchymosis here. The knee-jerks were lost. There was no change in the patient's condition in the next five days except that he had an attack of profuse and almost uncontrollable diarrhœa. On the fifth day after the accident the patient was rolled on his left side; a strong needle was inserted in the vertebral canal between the third and fourth lumbar vertebræ about 1½ centimetres from the middle line. Eight cubic centimetres of thick tar-coloured blood were removed. After this there was evident some restriction in the anæsthetic areas and a slight return of voluntary power in the extensors of the left thigh. The sphincters remained paralysed and the patient died suddenly four days after the puncture. An examination at the point of puncture showed that the needle had penetrated the subdural space, but had not wounded the cauda equina in any way. Dr. Killiani is of opinion that this simple procedure should be used in such cases with the object of relieving the spinal cord from the pressure of the effused blood.

THE EDWARD JENNER CENTENARY AT GLOUCESTER.

IT is extraordinary to note how at Gloucester, a town in which Edward Jenner resided for years, this centenary year of the discovery of vaccination is being kept. First, we find a board of guardians in fair weather when there was no small-pox about declaring themselves boastingly to be opposed to vaccination; then, frightened at their own mischievous default first recommending vaccination to the public by means of circulars and later, when still more frightened, actually turning right about face on all their former boasts and resolves and deciding to enforce the compulsory clauses of the Vaccination Acts. Secondly, we find that their experience—just 100 years too late—has been most bitterly bought, for, according to last week's papers, out of 90 deaths from small-pox in the hospital (there have been 118 in all in the city) 74 were in unvaccinated persons. Thirdly, we find that amongst this community which has been so long misled by the guardians there have within a few weeks been some 700 cases of small-pox, and that in the absence of any controlling vaccination the disease has seized that part of the town where the sanitary conditions are by no means worst, but where there was an undue proportion of unfortunate children who were unvaccinated. Fourthly, we find some thousands of pounds being spent in an attempt to check small-pox by hospitals, quarantining, and disinfection, but all in vain, for the disease goes on multiplying just the same; indeed, there were no less than 172 fresh cases last week. And, fifthly, we find that even some of those most responsible for the terrible loss of life among the unvaccinated are hurrying to get protection by vaccination for themselves. We leave those who have been so grievously injured by disease, maiming, and death, to apportion the blame. Here we only note with regret and shame that any British city, and above all Gloucester, should be in the state in which that city finds itself in the centenary year of Edward Jenner.

THE REGISTER OF MEDICAL STUDENTS.

NEXT in significance to the register of medical practitioners for any given year is the number of persons who have registered as medical students. The Medical Students' Register for 1895 has just been published, and shows that in that year no less than 1838 persons were so registered. Large as this number is—larger by three times than it was in the year 1865 when the registration of students commenced—it has often been exceeded. In the year 1879 for some reason or other, the number of registered medical students went up from 1699 to 2009. In 1891 the register contained the prodigious number of 2405, probably to be explained by the fact that the General Medical Council had decreed that students registering after Jan. 1st, 1892, should undergo a curriculum of five years' duration. The table at page 12 of the Students' Register shows that in twelve of the last seventeen years the number of medical students registering has been greater than in the last year. Still there is a great leap in the numbers of 1895 compared with the three preceding years. It is remarkable that, with the profession so crowded, the curriculum so expensive, and the examinations so numerous and difficult, so many students should still commence the study of the profession, though, of course, many whose names appear upon the register never really enter the profession itself. The percentage of registrations in the three divisions of the kingdom respectively for thirty years is as follows: in England, 49·96 per cent.; in Scotland, 30·34 per cent.; and in Ireland, 19·70 per cent. Of the 1838 who registered last year 955 registered in England, 575 in Scotland, and 308 in Ireland. It would seem that the increased severities of preliminary examination for medical graduates in the Scottish universities have not reduced the number of successful candidates.

AMONG the list of members of the Order of the Hospital of St. John of Jerusalem in England which, by the gracious sanction of Her Majesty the Queen, Sovereign Head, and Patron of the Order, appears in the *London Gazette* of Friday, March 27th, are the following names of members of the medical profession:—*Knights of Grace:* Surgeon-General W. G. N. Manley, C.B., V.C., Sir Edward Henry Sieveking, M.D., Mr. Thomas William Evans, M.D., Mr. Robert Brudenell Carter, F.R.C.S. Eng., Surgeon-Major-General Sir W. A. Mackinnon, K.C.B. (Director-General Army Medical Department), Inspector-General Sir James N. Dick, M.D., R.N., K.C.B. (Director-General of the Medical Department of the Navy), Surgeon-General Sir William Guyer Hunter, M.D., K.C.M.G., Sir Dyce Duckworth, M.D., LL.D., Mr. Thomas Wakley, F.R.C.S. Eng., Mr. William Collingridge, M.D., Surgeon-Major Lees Hall, A.M.S., Mr. William Bezly Thorne, M.D., Mr. Charles E. Milnes Hey, M.R.C.S. Eng., Sir William O. Priestley, M.D., LL.D., Deputy-Inspector-General Belgrave Ninnis, M.D., R.N., Inspector-General Henry Frederick Norbury, M.D., C.B., R.N., His Excellency Harry M. Crookshank Pacha, F.R.C.S. Edin., and Mr. Harry Pennington Hallows, M.D. *Esquire:* Mr. R. Vandeleur Kelly, F.R.C.S. Edin.

THE Duke and Duchess of York have arranged to be present at a grand *fête* which will be held in the building and grounds of the Middlesex Hospital, on July 1st, to commemorate the completion of the 150th year of the existence of the hospital and for the benefit of its new convalescent home at Clacton-on-Sea.

AT the instance of the Royal Commission upon Vaccination, which has been sitting for the last six years, and is now engaged in concluding its report, Dr. Sidney Coupland of the Middlesex Hospital has been instructed to inquire into, and report upon, the outbreak of small-pox in Gloucester.

AN influential committee has been formed to present Mr. George Knottesford Fortescue, the late superintendent of the reading-room of the British Museum, with an illuminated address expressive of the readers' hearty appreciation of the ability and courtesy which he ever manifested in the performance of the duties of his office. The committee would be very glad if any of the readers who are disposed to contribute a small sum towards this purpose, not exceeding 2*s.* 6*d.*, would kindly send such contribution to the treasurer, Dr. Samuel Rawson Gardiner, or to the honorary secretary, the Rev. Dr. Samuel Kinns, at his private address, 182, Haverstock-hill, Hampstead. There must be many of our readers who will be glad to learn of the opportunity that is thus offered to them.

MR. RICHARD BRAYN, L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Superintendent of the State Criminal Lunatic Asylum, Broadmoor, in succession to Dr. Nicolson, appointed a Lord Chancellor's Visitor in Lunacy. Mr. Brayn was a distinguished student and scholar at King's College. He has done much good work in Her Majesty's prison service, having been medical officer to Parkhurst and Pentonville prisons, assistant surgeon to Portsmouth and Millbank prisons, and governor and medical officer to Her Majesty's Female Convict Prisons, Woking and Aylesbury.

THE Metropolitan Asylums Board has just issued its expected report on the results from the use of antitoxin in diphtheria cases under treatment in the hospitals under their control. The report, which is full of elaborate tables, reflects great credit upon the medical superintendents of the six hospitals by whom it is signed, for the statistics are well arranged and the conclusions arrived at are judiciously moderate in tone and are free from any attempt to overstate the case in favour of antitoxin.

MR. S. OSBORN, F.R.C.S., has put on the agenda paper for the next meeting of the Metropolitan Asylums Board, to be held on April 11th, the following motion: "That a vote of thanks be given to the medical superintendents of the metropolitan fever hospitals of the Board for their excellent report upon the use of Antitoxic Serum in the treatment of Diphtheria, which adds so materially to the history of treatment in this disease as to be beneficial to the whole medical profession."

AT a sessional meeting of the Sanitary Institute, to be held at the Parkes Museum on Wednesday, April 15th, a discussion will be opened by Dr. J. F. J. Sykes, medical officer of health for St. Pancras, on the Factory and Workshops Acts and the Powers and Duties of Sanitary Authorities with regard to Workshops.

THE President of the Local Government Board has appointed Dr. Frederick St. George Mivart to the temporary medical inspectorship in his department which became vacant by the promotion of Dr. Wheaton to permanent office.

Pharmacology and Therapeutics.

ERODIUM CICUTARIUM IN HÆMORRHAGE.

DR. KOMOROVICH, writing in the *Vrach* of Feb. 29th, states that he has made considerable use of "Hemlock stork's bill," erodium cicutarium, in uterine hæmorrhage with excellent results, often after better known drugs, such as ergot and hydrastis canadensis, had failed. He believes that the effect of the erodium is to increase the elasticity of the muscular fibres and thus to favour their contraction. In one case where a polypus was the cause of the hæmorrhage, after a fortnight's treatment the tumour was extruded into the vagina, which had never occurred with other drugs previously tried. Twenty of the cases where erodium succeeded after the failure of ergot and hydrastis were due to metritis, but others were dependent on myoma and abortion. The preparation used was an infusion made with 12 parts of water to 1 of the plants, to which a few drops of peppermint were added to improve the taste. Of this a tablespoonful was prescribed every two hours. In no case were any unpleasant by-effects produced, though sometimes the medicine was continued for some weeks. The active principles of the plant are stated to be "an ethereal oil, a bitter principle called geramin, and tannic acid. It has been used as an astringent diuretic in dropsy."[1]

DRIED THYREOIDIN IN CORPULENCE.

Dr. Jevzykowski reports in the *Noviny Lekarski* ten cases of corpulence which he treated with the dried thyreoidin manufactured by Merk with excellent results. This preparation was given in doses of from 5 to 8 grains per diem, 10 grains of it being the equivalent of a thyroid gland from a medium-sized calf. It did not give rise to any unpleasant by-effects such as have been noticed by some observers. In one case, however, that of a patient with fatty degeneration of the heart suffering from occasional attacks of an anginal character, after some 300 5-grain doses had been taken, which had reduced the weight about 25 lb., a considerable amount of dilatation of the left auricle was diagnosed and the heart's action was weakened; this state of things lasted for about a fortnight, but afterwards the patient completely recovered and lost all tendency to anginal attacks. Speaking generally, Dr. Jevzykowski found that a very considerable decrease of weight was produced by the treatment, at all events where the patients were willing to give up their previous habits of over-eating and over-drinking. In one case more than 40 lbs. were lost in two months, and in another 30 lb. in three months. Dr. Jevzykowski also tried the dried thyreoidin in a case of inveterate ichthyosis, the skin regaining its ordinary character after five weeks' treatment. When the thyreoidin was left off, however, the disease began to reappear; another course of the remedy in increased doses again improved it, and when the patient was last seen there were no signs of any recurrence.

SALICYLATE OF METHYL ADMINISTERED BY CUTANEOUS ABSORPTION.

The facility with which the skin can absorb guaiacol has been shown to be very considerable, so that after painting the surface with this substance no less than forty-five grains of it have been recovered from the urine, a much larger dose than could have been introduced into the system by means of the stomach. This fact led MM. Linossier and Lannois of Lyons to try the effect of administering an anti-rheumatic drug—salicylate of methyl, the substance which forms nine-tenths of the ordinary Wintergeen oil—in a similar manner. It becomes transformed into salicylate of soda in the blood and is eliminated by the urine in the form of salicylic acid. It can also be detected in considerable quantity in the fæces. The daily elimination takes place in a regular manner during the course of treatment and no effect is produced on the skin by the applications. When sixty grains were painted on the surface of the thigh as much as twenty grains of salicylic acid were recovered from the urine within twenty-four hours. Like guaiacol, salicylate of methyl is absorbed by the cutaneous surface in a state of vapour, as can be readily shown by surrounding the limb with a cylinder of wire gauze. The method of application is very simple: the liquid is spread on the limb by means of a brush with or without the aid of a medicine dropper; the part is then covered with a layer of oiled silk or other impermeable tissue, over which cotton wool is fastened, and the whole left undisturbed for four-and-twenty hours. Sixty grains can be readily applied in this way, but if a larger dose is desired some lint is rolled round the limb, which becomes saturated with it. The absorption appears to be retarded by mixing lard or vaseline with the salicylate of methyl. The great advantage of administering medicines by the skin is that there is less risk of disordering the stomach than is the case when they are introduced into that organ, but it is only possible to employ this method in the case of drugs that are of a decidedly volatile nature.

THE FOUNDER OF "THE LANCET."

A BIOGRAPHY.[1]

CHAPTER XIV.

Wakley's Two Crusades.—Their Personal or Impersonal Nature.—The Procuring of Hospital Reports.—Specimens of this Department in Early Numbers of THE LANCET.—*The Scope of these Reports.*

As has been indicated, Wakley now found himself with two avowed objects of attack—the administration of the metropolitan hospitals and the constitution of the Royal College of Surgeons of England—and against each he waged a relentless war. In the columns of THE LANCET he poured scorn upon the educational system by which the students were compelled to pay large fees to support hospital surgeons who were unwilling or unable to teach them; and upon the platforms at certain public meetings he held up to ridicule a learned corporation which withheld from its members all the benefits it had been created to bestow.

The personal or impersonal character of his attacks must be recognised because it was identical in either crusade. It would seem, on the one hand, that the College, being a corporation, was open to censure that was not personal, and that no grave want of taste could be discovered in the designation of its constitution and behaviour as corrupt, inept, and impertinent. The officers of the College had a charter whereby they were guided in the administration of its affairs, and while they conformed to their charter the hardest things that were said about the institution reflected in no way upon them personally. It would seem, on the other hand, that attacks upon hospital administration were compelled to be of a highly personal nature, inasmuch as they were bound to resolve themselves into reflections upon the surgical skill or intellectual grasp and verbal felicity of the gentlemen who operated or lectured as members of the various staffs. Wakley desired to treat both sets of abuses in the same way, clearly perceiving that they had a common origin in the want of unity and general apathy of the body of the medical profession. This body he desired to arouse to the two facts that their teachers failed in duty towards them, and that the College of which the majority of them were members mulcted them in fees but withheld from them all their rightful privileges. No one glancing over the columns of THE LANCET during its first decade will have a moment's hesitation in deciding that Wakley, having to frame a method of indictment suitable to both sets of abuses, deliberately, even wantonly, chose the personal one always. Such an opinion would be wrong. His writings teemed with personalities, his speeches derived much of their point from the same element, but he tried in every way to preserve a middle course in his indictments of the Royal College of Surgeons and of hospital officials. Into his criticism of the corporation he certainly introduced much that almost amounted to personal abuse of individuals, while it would have been possible for him to deal with the legitimate complaints of the members of the College in a more abstract manner. But his reflections upon the administration in the hospitals were whenever feasible directed against systems, and although names were constantly introduced, and although personal remarks formed the basis of much of his fault-finding, yet it was the administration rather than the administrators that he designed to attack. Wakley, in fact, compromised, which means much, for he was the firm foe of compromise. He directed his reflections upon the College in many instances against the authorities by name, whilst more naturally he should have called the charter to account. He saw that to animadvert against the constitution of the College would not appeal to the minds of his audience sufficiently. Abuse of men was readily understood, but the drift of reproachful criticisms of a legal instrument was not so easy to follow. If his uncomplimentary speeches had only been aimed at the charter of the College no widespread agitation against the existent state of affairs would ever have sprung from them. But so personal a turn was not necessarily given to his reflections upon the administration of the metropolitan hospitals, for his readers could thoroughly appreciate what constituted good hospital management, and no point and piquancy were given to his strictures by the unnecessary introduction of names.

It will be understood that Wakley's two separate campaigns were conducted simultaneously in THE LANCET. For the purposes of this narrative his unrelenting criticism of the metropolitan hospitals is considered first, while his actions towards reform in the College of Surgeons will be described later, but it should be remembered that he was engaged in a double war all the time, for the feeling that he had foes on either side accounted for the fierceness of some of his onslaughts, and his perpetual air of watchfulness.

The Hospital Reports which it was announced in the preface of the second volume of THE LANCET would give a true and unbiased record from week to week of the practice within the walls of the various metropolitan institutions were watched with apprehension by all concerned in the administration of the institutions. Repeatedly denying that there could be any other reason for desiring to preclude him from reporting the cases that came under treatment in the hospitals save fear—fear lest malpraxis should be exposed or mismanagement and nepotism be revealed—he persevered steadily in his announced intention. Week after week there appeared in THE LANCET elaborate accounts of operations, abstracts of clinical lectures and outspoken reflections upon administrative details, every hospital in the metropolis receiving these unsolicited attentions, each being treated in exactly the same spirit—unceremoniously. Hospitals, said Wakley, are public places, supported by the piety and wealth of members of the public for the cure of their poorer brethren. And as public places they shall have publicity.

Wakley had some difficulty at first in obtaining these reports. He was himself a regular attendant at the Borough Hospitals and the author of many of the early reports of operative procedures at their theatres, but he was most careful to make his survey of London practice from week to week a comprehensive one, so that he had to employ reporters to work for him. His difficulty in doing this was twofold. It was necessary that the man who reported for him should be thoroughly competent and privileged to go in and out of the wards at will. It was necessary also that he should be able to keep his identity unrevealed in view of the great opposition that had been manifested by many of the hospital surgeons to the publicity threatened for their work. Mr. Travers, for instance, had frankly told the students of the Borough Hospitals that he would urge the expulsion from the united classes of any student detected in supplying THE LANCET with reports of lectures or of operative proceedings, while Mr. Abernethy had expressed the sentiments of himself and his colleagues at St. Bartholomew's Hospital by terming the paid reporter of THE LANCET "a hireling," and bidding him stand forth to receive back his fees, which the medical school declined to keep having regard to their tainted source. But as against these facts the students recognised in THE LANCET a strong friend to their cause, so that Wakley obtained many offers of assistance

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., and XIII. were published in THE LANCET, Jan. 4th, 11th, 18th, and 25th, Feb. 1st, 8th, 15th, 22nd, and 29th, March 7th, 14th, 21st, and 28th respectively.

Digitized by Google

and had from the beginning many would-be contributors to choose from. It was his practice to employ and pay highly a senior student at each hospital to make regular reports for him, while he himself or some trusted member of the staff would make a round of the various operating theatres, dropping in now on this and now on that institution that he might judge for himself of the accuracy of his reporter's work.

All who possess or have access to the back numbers of THE LANCET can read for themselves the way in which these reports were done; and if they can subdue the innate savagery of man so far as to pass over the scathing accounts of some luckless surgeon's error to peruse the approving records of successful operations and well-directed innovations for the good of patient or student, they will certainly agree that from a journalistic point of view this department of THE LANCET formed a remarkable journalistic feat. Shorthand had not, under Taylor's system, reached its present pitch of excellence; telegraphy was unknown; London possessed no remarkable facilities for progression from place to place; no papers, medical or lay, gave information in the form of a diary, from which could be learned the day and hour at which in the interests of science a reporter ought to be in a given place—but in spite of all these drawbacks, and with the additional disability upon him that if his agents were discovered all obstacles would be officially placed in their way, Wakley produced week by week a record of doings within the jealously guarded walls of the metropolitan hospitals.

It will be well here to give the results of a brief perusal of the reports up to the year 1828. In this way an estimate of their value can be arrived at, for we shall be able to appreciate the amount of good that such a system of regular criticism must have worked, and the amount of indignation and vexation that such a violation of their privacy must have aroused in the officials.

In March, 1825, a man was admitted into St. George's Hospital suffering from pneumonia. He was bled in the arm by the dresser and during the little operation the brachial artery was wounded. The man was placed under one of the surgeons, who, on consultation with the physician, considered that the pulmonary trouble was too severe to warrant him in disturbing the patient by tying the brachial artery—obviously the only safe course to pursue under the unfortunate circumstances. A tight bandage was applied to the arm above the wound instead of a ligature being placed upon the vessel. The bandage remained three days untouched, when, the circulation having been occluded, mortification set in and the patient died. A coroner's jury brought in a verdict that the man died from the accidental opening of an artery in the arm *and from the want of proper attention*. Four months later a still worse case of malpraxis occurred at the same hospital. A man was admitted to the accident ward whose right knee was cut with a broken bottle. The house surgeon thought that an artery was severed and applied a tight bandage. This patient was under the care of the same surgeon, who did not, as it afterwards transpired, examine the knee himself, but left the bandages undisturbed, despite the fact that the leg was much swollen *above* the bandage. The bandage was not removed for five days, and when it was the limb was in a terrible condition. The man died and an inquest was held, at which it was elicited that the surgeon had trusted entirely to his house-surgeon, and that the younger gentleman's statements were not to be relied upon. A juror, in spite of the warnings of the coroner that he might be proceeded against for libel, persisted that there had been gross neglect in the treatment of the unfortunate man. The coroner pressed for a verdict without comment, but ultimately the jury returned that "the deceased received a cut on the knee by accident and from the effects of improper surgical treatment and neglect his death was produced."

Upon these cases THE LANCET made exceedingly severe comments and used freely the names of all concerned, holding their owners up to the contempt of the profession. Almost at the same time a man died in the Middlesex Hospital after an operation for strangulated hernia, and the writer of THE LANCET report of the case definitely accused the senior surgeon of the hospital of having, as a first count, neglected the case, so that the unfortunate man's plight was hopeless when the operation was undertaken, and having, as a second count, performed the operation in an exceedingly unskilful manner. The writer of the report finished by leaving discussion of the particular instance to say of the operative proceedings at Middlesex Hospital generally that it was the regular practice at Middlesex for the surgeon to wait before operating until all chance of recovery was gone, and that not more than one patient had recovered from an operation to relieve a strangulated hernia in the hospital for two years!

Several examples of malpraxis at Guy's Hospital and St. Thomas's Hospital were detailed at length. Two similar cases of compound fracture of the bones of the leg were admitted, one to the wards of Guy's Hospital and the other to the wards of St. Thomas's Hospital, in April, 1826, the treatment of the last of which was made the subject of severe comment. In the former the surgeon was stated to have delayed operating until too late and then to have amputated in a clumsy manner. In the latter he is taken to task roundly for having omitted to notice that the patient was going downhill fast owing to an extensive abscess having formed, unsuspected by everybody, on the back of his thigh. All the names are given in full, and the editorial comments are of the freest and bitterest.

The comments show the personal way in which Wakley dared to deal with these matters, and anyone who chanced to read them might be tempted to judge that he had no other way. As a matter of fact, however, his treatment of hospital administration was much more judicious than would be gathered from the perusal of the denunciatory articles.

"Nothing is more easy than to show," said Wakley, "that our hospital system is fundamentally wrong, from the surgeon to the surgery man and from the physician to the apothecary's apprentice. The manner in which the appointments are managed is the most nefarious and in utter violation of every principle of justice and common sense. For example, an advertisement announces the resignation of a medical officer of some hospital (which, by-the-bye, too seldom happens), and how do the rival candidates arm themselves for the contest? Not by trying to outvie each other at a public disputation, nor even at an examination in a committee-room, but by beating up the quarters of their brewers, their bakers, their tailors, and their other tradesmen, and in proportion as the candidates or their friends have influence with this class of persons, or, in other words, have a good *city connexion*, so are they according to the usual doctrine of chances secure of the vacant post. Now, then, men who can know nothing of the real qualifications of the candidates are the real electors of physicians and surgeons to public hospitals; and what is the consequence? What we too often see—that ignorant pretenders exclude men of sound talent, to the great injury of science and the great sacrifice of human life."

All of this Wakley set himself to demonstrate. The fact that the wrong men were chosen as medical officers to the hospitals could only be proved to demonstration by reporting examples of their failures. This he did regularly and in the unsparing manner of which examples are given above. But this only formed part of the work that he designed to carry out by the publication of the Hospital Reports. The general failings of the institutions as educational and administrative establishments also received uncomplimentary attention. That surgeon's pupils were

Digitized by Google

idle and abused the privileges that they had purchased; that dressers, having no proper supervision, very usually neglected their duties; that the house-surgeons being chosen from these gentlemen were frequently ignorant; that the nursing was often bad, and that no proper attention was paid to the diet of the patients; that the buildings of the hospitals were sometimes uncleanly and insanitary,—these and other unpleasant facts he brought to light by his elaborate system of reporting and treated with proper out-speaking. Can it be wondered at that within the walls of the hospitals, by all save the students for whom he fought, his name was a synonym for mischief-maker and agitator?

(To be continued.)

THE NEW PHOTOGRAPHY.

DIRECT VISION BY MEANS OF THE ROENTGEN RAYS.

BY J. MACINTYRE, M.B., C.M. GLASG., F.R.S. EDIN.

Shadows obtained of the Extremities and Trunk.

SINCE my last communication I have had several screens of calcium tungstate prepared, and as a number of experimenters have asked for information about the preparation of the crystalline form, the following notes may be useful. The last preparation I mentioned in THE LANCET was made for me by Messrs. Barrs and Sallock, but Mr. J. Frank Bottomley has kindly given me a larger quantity of the crystals and he prepares it after Manross's method.[1] It consists in fusing together the anhydrous sodium tungstate and calcium chloride, the latter in excess. The sodium chloride and excess of calcium chloride are dissolved out and crystalline calcium tungstate is left behind to be filtered off and dried. The crystals are a mixture of needles and octahedra, but the latter can only be seen with the microscope. This makes an excellent screen, but I still find the potassium platino-cyanide the best. The following cases for diagnosis have come under my observation since last week. In one, a suspected case of unreduced dislocation of the phalanx, Dr. Renton and Dr. Somerville saw distinctly (without photographs) that the parts were in proper position. In another I showed to several medical men an old fracture of the forearm with the fragments of the bones in an altered position. Following up my former experiments, I may say that not only do I find it extremely important to prepare the screen properly, but the distance of the Crookes's tube from the object must receive the most careful attention. By regulating the distance one can get very distinct shadows, but of course the further off the source of the "x" rays (i. e., the Crookes's tube) the less do we get fluorescence. I have now seen all the bones of the two extremities, and with such definition as to be quite practical for many surgical purposes. What is still more important to note, I have seen distinct shadows of the vertebral column and ribs. The sternum is also seen if the Crookes's tube be placed behind instead of in front. In the latter case I could see the shadows of the buttons on the clothes as well through the body. It is an easy matter to penetrate the head, but, as I mentioned in the last article, we still need further improvement in the source of the rays. A little more power from the tube is what we now require. One of the most beautiful results I have got was shown to several of my friends during the week when the different movements at the elbow were seen. These could be distinctly made out and the movements of extension and flexion were extremely plainly demonstrated.

Mr. George Heaton, F.R.C.S. Eng., surgeon to the General Hospital, Birmingham, sends us the following account of a case where a foreign body in the wrist was localised and successfully removed by the aid of Roentgen's method of photography.

"A man aged thirty-two years, whilst at work on March 18th was struck by a piece of metal on the ulnar side of the left wrist, which made a small wound which bled freely. He was removed to the General Hospital, Birmingham and the wound examined carefully by the house surgeon on duty. No foreign body could be detected either by palpation or with the probe. The wound was dressed antiseptically and the arm kept at rest in a splint. On March 25th a photograph (which I enclose) was taken by Mr. Hall Edwards, exposure of one minute and forty-five seconds being given. The foreign body can be seen distinctly lying in the palmar aspect of the semilunar bone. Even after localisation by Roentgen's method the foreign body could not be felt through the unbroken skin. The same day an anæsthetic was administered and a small incision made in the situation, as shown in the photograph. The foreign body, a sharp thin piece of steel, was found at once lying deeply amongst the flexor tendons of the wrist over the semilunar bone. The wound was closed and has since healed."

*** We do not reproduce the photograph, as it presents no features differing from numerous other photographs that have appeared in our pages and elsewhere. The foreign body is, however, very well shown in it."—ED. L.

EXPERIMENTAL RESEARCHES OF THE ROYAL COMMISSION ON TUBERCULOSIS.

II.—MILK.[1]

THE danger to public health arising from the consumption of tuberculous milk has been generally, and probably correctly, estimated to be considerably greater than that which arises from tuberculous meat. Whether the danger is confined to milk from cows with tuberculous udder disease or exists also in milk from tuberculous cows with normal udders is a matter which has given rise to considerable discussion. Some cases have been reported by Professor Bang and others where a tuberculous cow with an apparently healthy udder gave demonstrably infective milk. A large number of such cases would doubtless be conclusive on this point, but so far very few have been recorded, and the possibility that in these cases the bacilli owed their existence in the milk to undetected tuberculous deposits in the mammary glands must not be overlooked. The experimental researches of the Royal Commission on Tuberculosis tend to show that tuberculous udder disease must be established before the milk becomes infective. In Part III. of his inquiry, Dr. Sidney Martin gives particulars of experiments with milk of eight cows, one with "mild," five with "moderate," and two with "advanced and generalised" tuberculosis—all shown to be free from udder disease post mortem. The milk of two cows was distinctly abnormal: one with "advanced and generalised" tuberculosis gave a yellow milk with considerable excess of fats and deficiency in lactose; another with "moderate" tuberculosis, gave milk with a large excess of albumin and a corresponding deficiency in casein. Milk of the remaining six cows was in no case markedly abnormal to chemical and physical tests. Tubercle bacilli were not to be found in the milk of any of the eight cows. The milk of each was tested by inoculating experimental animals; of a total of twenty-eight guinea-pigs and rabbits thus inoculated none developed tuberculosis. It was also used to feed a number of guinea-pigs, each guinea-pig receiving about a litre of milk. In addition, milk of each of five of these cows was given as food to pigs, which are peculiarly apt to contract tuberculosis from feeding. The smallest amount of milk consumed by any one pig was seven and a half litres, while as much as fifty-six litres (and this from a cow with "advanced and generalised" tuberculosis) was given to another. None of the pigs or guinea-pigs thus fed became tuberculous.

Two other tuberculous cows had been purchased in the belief that they had tuberculous udder disease, but examination of the udder post mortem showed that the affection was a non-tuberculous interstitial mastitis. The milk of these cows similarly tested proved to be uniformly non-infective. Milk of cows with tuberculous udders, on the other hand, was found to be extremely virulent. Five such cows were obtained, twenty-one animals were inoculated with milk from one or other of them, and all became tuberculous. In three cows the virulence of the milk proved as great in the

[1] No. I. (Meat) was published in THE LANCET of Feb. 29th, 1896.

Digitized by Google

feeding experiments, for in each case all the animals fed became tuberculous. Tubercle bacilli were found in the milk of each of these three animals. Of the remaining two, the milk of one was infective to three out of the nine guinea-pigs and to the one pig fed with it, while the milk of the other was consumed by two guinea-pigs only, both of which remained healthy. Bacilli had not been found in the milk of either of the last two cows, although in each case the infectivity of the milk had been demonstrated by inoculation. The disease produced in the test animals was in every case a rapid form of tuberculosis.

"The milk of cows with tuberculosis of the udder possesses a virulence which can only be described as extraordinary. All the animals inoculated showed tuberculosis in its most rapid form, such as it is seen after inoculation with a recent tubercular lesion, and this was the case even with Cows 8 and 24, the milk of which gave irregular results with feeding, so that in one case (Cow No. 8) it was possible to diagnose as tuberculous a local lesion produced by milk injection, even though the guinea-pig lived only nine days, tubercle bacilli being found in the thickened tissues at the seat of injection."

Dr. Martin found no diminution in virulence to test animals when this milk was diluted to four times its bulk with healthy milk; indeed, a dose of even 0·05 to 0·1 c.c. diluted with healthy milk was sufficient to produce tuberculosis. He also experimented with skimmed milk, buttermilk, and butter prepared from tuberculous milk. Each of these products produced well-marked tuberculosis both by feeding and by inoculation in all the animals experimented on, and it is important to note that the virulence of skimmed milk, butter milk, and butter was not notably decreased by a previous addition of healthy milk to the tuberculous milk employed in their manufacture.

We do not get much information from these inquiries as to the physical characters of the tuberculous udder. Dr. Martin observes:—

"Tuberculosis of the udder is a slow, painless growth. A disease of the udder which is slow in development, taking weeks or months to affect a large portion of the udder, and occurring in a tuberculous animal, is in all probability tuberculosis. Anything more definite than this cannot be said."

Absence of tenderness in the growth and enlargement of the supra-mammary glands are neither diagnostic of the nature of the enlargement. As regards the milk itself, diminution in its quantity, although common in tuberculosis of the udder, frequently occurs in other morbid conditions of the cow; chemical analysis in certain cases can demonstrate some abnormality, but does not in any case indicate that the abnormality is due to tuberculous udder. Examination of the milk for bacilli might have been expected to demonstrate the existence of the disease in all cases, yet in the two cows already referred to repeated examination for bacilli, with and without the aid of the centrifugal machine, was made without result, the milk from both cows being none the less infective to test animals. In fact, Dr. Martin shows, if tubercle bacilli are not found the only trustworthy test is the inoculation of experimental animals with the suspected milk. Obviously this test is not one which can be readily applied by the farmer or veterinary surgeon to cases of suspected disease of the udder. Dr. Martin recommends, therefore, that a cow affected by any form of disease of the udder should be excluded from the dairy farm, not only where there is an obvious enlargement (of whatever nature) in any part of the udder, but also when the milk from one or more quarters is observed to fail either in quantity or quality. The diseased cow thus set apart can then be thoroughly examined by a person competent to apply the necessary tests. But, in reality, the question is a wider one, for any tuberculous cow, no matter what the stage of its tuberculosis, is liable to have its udder affected. As pointed out in these inquiries, the onset of udder tuberculosis is insidious and may be very difficult of detection. Nothing short of a knowledge of all the tuberculous cows of a dairy, their separation from other cows, and a frequent inspection by competent observers would serve to minimise the risk of the milk they supply—if, indeed, the milk of any tuberculous cow is allowed to be consumed at all.

The effect of heat on tuberculous milk forms the subject of an elaborate research by Dr. Sims Woodhead (Inquiry III., Parts 8 and 9). He used for experiment both milk from cows with tuberculous udders and milk rendered tuberculous artificially by intimate admixture of tuberculous sputum or of portions of tuberculous organs very finely divided. He found that of the two the natural tuberculous milk in the raw state proved to be more uniformly infective. Dilution with healthy milk appeared in some instances to reduce, and in others to make no difference to, the infectivity of tuberculous milk. Dr. Woodhead accepts as proved that raising milk to 100° C. even for a single instant will completely kill tubercle bacilli contained in it; and he adopts the explanation of Hodenpyl and Prudden and others that "tubercles" produced in animals by inoculation of boiled tuberculous milk are the result of necrosis round the bodies of dead bacilli and do not contain the living microbe. In his own experiments he kept tuberculous milk (natural or artificial) in a water-bath specially contrived for the purpose for given periods of time at each of a long series of temperatures from 50° to 90° C. He then tested the milk so treated in each instance by inoculating and by feeding test animals with it. The results of intra-peritoneal injection of guinea-pigs are instructive. Here the effect of heating the milk to a temperature short of 100° C. was manifested in two ways. In the first place such partial heating rendered the milk capable of infecting only a small proportion of the test animals, whereas the raw milk had rendered every animal experimented on tuberculous. The proportion of animals attacked was smaller as the temperature to which the milk was raised was greater; it was also smaller as the time at which the milk had been kept at a particular temperature was longer. In the second place the test animals attacked under these conditions suffered from a slowly progressing and limited tuberculosis, the slowest progress and the most marked localisation of lesions being obtained with milk heated to the highest temperature and for the longest time short of altogether destroying its infectivity. Dr. Woodhead found evidence of attenuation of virulence in the way indicated when the milk had been kept for some time at even as low a temperature as 50° C.

Although the character of the disease produced was perhaps modified, and although in some cases the proportion of test animals affected was small, tuberculosis was nevertheless produced in guinea-pigs by intra-peritoneal injection of milk which—to instance a few of Dr. Woodhead's results—had been heated momentarily to 90° C., heated for twenty-two minutes to 75° C., for half an hour at 70° C., three hours at 65° C., or twelve hours at 50° C. After heating for a longer time at each of these temperatures the milk appeared innocuous to guinea-pigs. It was found, however, that the results of feeding pigs with tuberculous milk afforded a still more delicate test of infectivity than inoculating guinea-pigs. The results of feeding pigs are noteworthy and may be gathered from Dr. Woodhead's table (lxxv).

Feeding Experiments with Pigs, using Artificial Tuberculous Material heated to Different Temperatures for Various Times.

Temperature.	5 min.	2½ min.	10 min.	15 min.	20 min.	30 min.	40 min.	45 min.	1 hour.
60° C.						+			+
65° C.					+		+		
70° C.		+		+		-		+	
75° C.	+		+	+					
80° C.	+		+						

+ = Where experiments gave positive results.
- = Where experiments gave negative results.
Where spaces are left blank no experiments were made.

From this table it will be observed that artificial tuberculous milk kept at 80° for ten minutes or for a quarter of an hour at 75° still remained infective when given to pigs as food. For any indications to the contrary furnished by these experiments, the infectivity to pigs may still exist in milk raised to higher temperatures and heated for longer periods. This is all the more important as the analogy between the manifestations of the modified tuberculosis produced in the pig by this imperfectly heated milk and the "strumous" glands and other chronic tuberculous lesions of children and adults is an exceptionally close one—a point fully insisted upon by Dr. Woodhead. His experiments suggest doubts of the ability of several processes applied to milk under the name of "sterilisation" or "Pasteurising" to destroy the infectivity of tuberculous milk to man.

KINGSBURY v. HART.

THE Fylde Medical Society, of which Dr. Kingsbury is the Hon. Secretary, held a special meeting in Blackpool on March 20th, 1896, to hear an explanation from him of the charges against him in the *British Medical Journal* of Jan. 18th, 1896, deeming it more satisfactory that his conduct should either be vindicated or condemned by members of his own profession than that the verdict of a lay jury, already given in his favour at the Manchester Assizes, should be accepted as final.

Dr. Kingsbury dealt fully with the anonymous accusations of "Ethics," and the comments thereon by the editor of the *British Medical Journal*, and gave a detailed account of his long connexion with both the hydropathic establishments of Blackpool, and answered all the questions submitted to him by the members of the society.

Mr. Day proposed: "That, having heard the explanation given by Dr. Kingsbury, the Fylde Medical Society hereby unreservedly accepts the same as satisfactory." Mr. Eason seconded the proposition and expressed his perfect confidence in the hon. secretary, who had always taken the keenest interest in maintaining the ethics of the profession. The resolution, having been supported by Dr. Brown, Dr. Blundell, Mr. Dunderdale, Mr. Lenihan, and Mr. Calvert, was carried unanimously.

Dr. Stott then proposed: "That, in the opinion of this society, the attack of 'Ethics' upon Dr. Kingsbury and the method adopted by 'Ethics' in making such attack are to be strongly condemned." Dr. McIntosh, having seconded this resolution, it was also carried unanimously.

Dr. Kingsbury then read a letter dated March 14th, 1896, which he had addressed to the editor of the *British Medical Journal* the moment that gentleman had publicly stated that he accepted the Manchester jury's verdict as a just one. To this letter an answer was received from the assistant editor, under date March 19th, 1896, saying: "Your letter of March 14th, addressed to the editor of the *British Medical Journal*, has been very carefully considered, but it has appeared to be on the whole undesirable to publish it in the *British Medical Journal*. In compliance with your request the letter is herewith returned."

A resolution was then proposed by Mr. Richardson, seconded by Mr. Lenihan, and unanimously carried, condemning the action of the *British Medical Journal* in refusing to publish Dr. Kingsbury's letter of March 14th, 1896.

At the conclusion of the meeting Dr. Kingsbury received the warmest congratulations of his medical brethren.

THE ANGLO-EGYPTIAN NILE EXPEDITION.

No time is being lost in vigorously prosecuting this expedition. The passage of troops and war material up the Nile continues to be actively carried on. It is expected that the whole of the force composing the Dongola column will be concentrated at Sarras, thirty-five miles beyond Wady Halfa, within a month. The railway to Akasheh is being pushed on and troops and provisions are being rapidly transported to the front. Those of our readers who are acquainted with the way in which the Egyptian authorities pack their troops on board steamers and barges will readily understand the large numbers that can be transported under such circumstances compared with those of British soldiers. So far as the present expedition has gone, the organisation and transport arrangements have been working extremely well. Assouan has been, and still is, a scene of great activity, and a large camp exists at this station. Sir H. Kitchener, the Sirdar of the Egyptian Army, is organising the expeditionary force at Wady Halfa, where a British regiment should have arrived by this time. A body of Dervish cavalry recently reconnoitred in the vicinity of Akasheh, but retired on being fired upon by the Egyptian troops. The news of the advance is said to have caused great excitement at Dongola. There are now three battalions of Soudanese infantry, with several squadrons of cavalry, a battery of artillery, and a camelry corps at Akasheh, and additions to the force at this station are being rapidly made. The health of the troops is stated to be very good so far. The heat is only great at midday, but the hot wind from the south-west—the khamsun—is due at this season and the temperature and discomfort, and probably the inefficiency from sickness, may be expected to increase on its appearance. Large quantities of medical and other stores for the hospital service have been forwarded with the expeditionary force, and with the number of medical officers already in Egypt and those arriving there from this country it is believed that the expedition will be well provided in these respects. The military authorities in Egypt have had a good deal of experience of military expeditions up the Nile and are practically acquainted with their requirements. The major portion of the force, consisting of Soudanese and Egyptian troops, are accustomed to and stand the climate well; but this cannot, of course, be said of the British troops, although the results of our previous expeditions have shown that with proper care and hygienic precautions our soldiers withstand the climate much better than might be anticipated. Everything connected with field service arrangements in these respects is much better understood, and much greater care is taken nowadays in regard to health and sanitation, than was formerly the case. Still, as everybody knows, the heat in these regions is very great during the approaching season, and a certain amount of disease must inevitably follow.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Crewe Urban District.—Mr. Herbert Jones, the medical officer of health of this important district, which has now a population of some 37,000, is given by the sanitary authority somewhat difficult tasks to perform. To cope with an epidemic of scarlet fever, or, indeed, of any other disease, without the means of isolation, or even the assistance of the Notification Act, is a thankless and hopeless labour from which we should ask to be excused. Yet this was the task which Mr. Jones was left to carry out in 1895. School closure had to be resorted to in order to check the spread of the disease, but, as Mr. Jones observes, this step really took away from him the only source of information as to the distribution of the disease which in the absence of notification he possessed. It is obviously impossible for the many points which suggest or contra-indicate school closure in any given epidemic to be ascertained without notification, and we suspect that much injustice is done to elementary education by what must, in the absence of notification, be more or less a step in the dark. The exact distribution of cases in a district is one of the essential pieces of information with regard to any intelligent application of the powers vested in the medical officer of health as to school closure. In the matter of isolation accommodation we are glad to be able to record that the town council has now obtained the consent of the Local Government Board to borrow the necessary funds, and that there is every prospect of the town being shortly provided both with a hospital for small-pox and one for other infectious diseases. The matter of notification still seems to hang fire, in spite of the fact that Mr. Jones has urged on the sanitary committee upon numerous occasions the necessity for the adoption of the Act. The committee seem to think that it will be well to delay notification until after the erection of the fever hospital; in other words, they advocate in principle the plan of building stables before the number of horses which they will be called upon to provide for is known.

Kingston-upon-Thames Urban District.—Mr. Beale Collins reports that the most important event of the year 1895 was the severe frost which brought home to the community of his district the disabilities under which they labour in not possessing the control of their own water-supply. Mr. Collins states that during the stoppage of the water by frost he measured the depth of the main in a certain road and found it to be but eight inches from the surface, and in no place in the road in question did the pipes when uncovered appear to be at a greater depth than eighteen inches. In the matter of isolation accommodation the sanitary authority has purchased a site, and Mr. Collins urgently impresses

Digitized by Google

upon the corporation the necessity for the erection of a hospital; he suggests that arrangements should be made with adjoining authorities for the provision of joint accommodation for small-pox. In order to diminish the risks of infection through the agency of books from the public library, it has been arranged that the inspector of nuisances shall forward to the librarian the names of all cases of infectious disease notified. When the patient recovers the books are returned after disinfection to the librarian. One case of typhoid fever in Kingston was attributed to the consumption of oysters.

Kensington Sanitary District.—In his last monthly report Dr. Dudfield draws attention to an allegation which has been made in some quarters that the district of Kensington is suffering from "over-inspection." In order to refute this extravagant statement he has drawn up a short report showing the average number of persons to each inspector in the several metropolitan sanitary districts. He shows that in three districts there is one inspector to less than every 10,000 persons; in eleven districts there are between 10,000 and 15,000 persons to each inspector; in eleven other districts between 15,000 and 20,000; in twelve districts between 20,000 and 25,000; in three districts between 25,000 and 30,000; and in the remaining two districts there are more than 30,000 persons to each inspector. Kensington has one inspector to every 24,224 persons.

Ampthill Rural District.—Mr. C. M. Fegen reports two outbreaks in his district, one of scarlet fever and the other of measles, which diseases he regards as having been introduced by "holiday children," and he advises that some steps be taken to guard against these annual visitors acting as introducers of infectious disease. He thinks that children should not be allowed to be sent from houses where infectious disease has been present during the previous six weeks, but this seems to us a little impracticable. Mr. Fegen in discussing questions of water-supply refers to the risks that are run in cases of draw-wells from the use of pails which are not kept solely for the purpose. He advocates the use of pumps, or where these are not possible the provision of a permanently fixed pail for each well.

Maldon Rural District.—Dr. Thresh, in his annual report for 1895, draws attention to the menace which exists to the public health in this district from the presence in it of the "Peculiar People," whose faith in supernatural agencies leads them to neglect the assistance of natural laws as expressed in the practice of the physician, and as a consequence the disregard of the provisions of the Notification Act. Dr. Thresh records an instance in which two children died suddenly under conditions strongly suggestive of diphtheria. No medical man was called in, and the coroner, after causing inquiries to be made, held no inquest in either case. One case was registered as "due to influenza and sore-throat," the other to "tubercular disease since birth." We would certainly deal gently with most questions involving the conscientious scruples of any sect; but a matter like this, which in numerous ways threatens the public health—to say nothing of the gross injustice to individual children,—cannot be lightly treated, and we should be glad to see an example made of some of these Essex "Peculiars." Dr. Thresh adds that as trouble has arisen in other parts of Essex from the failure of these misguided people to call in a medical man he proposes to deal with the subject fully in his reports on this county.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6611 births and 3099 deaths were registered during the week ending March 28th. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 20·7 to 19·2 per 1000, further fell last week to 18·8. In London the rate was 17·9 per 1000, while it averaged 19·3 in the thirty-two provincial towns. The lowest rates in these towns were 11·7 in Brighton, 12·2 in West Ham, 13·2 in Burnley, 13·6 in Nottingham, and 13·7 in Swansea; the highest rates were 23·7 in Liverpool, 24·3 in Birkenhead, 25·6 in Preston, and 26·1 in Manchester. The 3909 deaths included 631 which were referred to the principal zymotic diseases, against 636 and 578 in the two preceding weeks; of these, 267 resulted from measles, 177 from whooping-cough, 87 from diphtheria, 41 from scarlet fever, 31 from diarrhœa, 27 from "fever" (principally enteric), and 1 from small-pox. No fatal case of any of these diseases was recorded in Brighton; in the other towns they caused the lowest death-rates in Portsmouth, Blackburn, Nottingham, and Preston, and the highest rates in Birmingham, Salford, Oldham, Sunderland, and Birkenhead. The greatest mortality from measles occurred in Bristol, Manchester, Salford, Sunderland, Oldham, and Birkenhead; from scarlet fever in Bolton; and from whooping-cough in Cardiff, Derby, Leicester, Salford, and Sheffield. The mortality from "fever" showed no marked excess in any of the large towns. The 87 deaths from diphtheria included 51 in London, 5 in Birmingham, and 3 each in West Ham, Bristol, Liverpool, Manchester, Leeds, and Hull. One fatal case of small-pox was registered in Bradford, but not one in London or in any other of the thirty-three large towns. There were 33 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, March 28th, against 52, 42, and 43 at the end of the three preceding weeks; 2 new cases were admitted during the week, against 13, 4, and 9 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2744, against 2857, 2764, and 2773 on the three preceding Saturdays: 224 new cases were admitted during the week, against 244, 217, and 277 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined in the three preceding weeks from 433 to 345, further fell to 285 last week, and were 166 below the corrected average. The causes of 48, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Salford, Bradford, Leeds, Newcastle-upon-Tyne, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Wolverhampton, Birmingham, Birkenhead, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·6 per 1000 in each of the two preceding weeks, declined again to 18·9 during the week ending March 28th, and almost corresponded with the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·8 in Dundee and 16·8 in Greenock to 20·8 in Glasgow and 25·6 in Perth. The 552 deaths in these towns included 21 which were referred to whooping-cough, 14 to diarrhœa, 6 to scarlet fever, 6 to measles, 4 to "fever," 1 to diphtheria, but not one to small-pox. In all, 52 deaths resulted from these principal zymotic diseases, against 72 and 70 in the two preceding weeks. These 52 deaths were equal to an annual rate of 1·8 per 1000, which was 1·2 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 35 and 29 in the two preceding weeks, further declined to 21 last week, of which 13 occurred in Glasgow and 4 in Aberdeen. The 14 deaths from diarrhœa corresponded with the number in the preceding week, and included 8 in Glasgow. The fatal cases of scarlet fever, which had been 6, 7, and 4 in the three preceding weeks, rose again to 6 last week, all of which were recorded in Glasgow. The fatal cases of measles, which had increased from 6 to 13 in the three preceding weeks, declined again to 6 last week, and were all registered in Glasgow. The 4 deaths referred to different forms of "fever" showed a decline from those returned in recent weeks, and included 2 in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 116 and 115 in the two preceding weeks, declined to 107 last week, and were 92 below the number in the corresponding week of last year. The causes of 23, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28·3 and 25·4 per 1000 in the two preceding weeks, further declined to 24·8 during the week ending March 28th. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 25·3 per 1000, the rate during the same period being 19·5 in London and 17·7 in Edinburgh. The 166 deaths registered in Dublin during the

Digitized by Google

week under notice were within 4 of the number in the preceding week, and included 7 which were referred to the principal zymotic diseases, against 10 and 7 in the two preceding weeks; of these, 3 resulted from diarrhœa, 2 from scarlet fever, 1 from diphtheria, 1 from "fever," but not one either from small-pox, measles, or whooping-cough. These 7 deaths were equal to an annual rate of 1·0 per 1000, the zymotic death-rate during the same period being 3·6 in London and 0·6 in Edinburgh. The 3 fatal cases of diarrhœa exceeded the number recorded in any recent week. The deaths referred to scarlet fever, which had been 4 and 1 in the two preceding weeks, rose again to 2 last week. The 166 deaths in Dublin last week included 21 of infants under one year of age, and 40 of persons aged upwards of sixty years; the deaths of infants slightly exceeded the number in the preceding week, while those of elderly persons showed a decline. Five inquest cases and 3 deaths from violence were registered; and 61, or more than a third, of the deaths occurred in public institutions. The causes of 10, or rather more than 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN CATHCART GARNER, M.B., is seconded for service with the Egyptian Government.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Colonel A. F. Churchill, A.M.S., is brought on the Administrative Medical Staff of the Army, vice Surgeon-Colonel T. Maunsell, appointed Principal Medical Officer, Malta. Surgeon-Major John Anderson becomes Joint Civil Surgeon, Simla, when Surgeon-Major Cunningham vacates that appointment this month. The latter officer goes to Patiala in place of Surgeon-Major Owen, who goes home on leave. The services of Surgeon-Captain W. C. Sprague, M.D. (Bombay), are placed temporarily at the disposal of the Government of Bombay. The services of Surgeon-Captain P. C. Gabbett (Madras), are placed at the disposal of the Government of Madras. Surgeon-Captain A. A. Sutton, A.M.S., has been transferred from the Poona district to the Aden district.

NAVAL MEDICAL SERVICE.

The following appointment is announced:—Surgeon P. B. Handyside to the *Fox*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain James Denholm, M.B., having resigned his Volunteer appointment, ceases to be an officer of the Army Medical Reserve of Officers.

THE ARMY MEDICAL SERVICE.

The following memorial from the Medical Faculty of Queen's College, Belfast, as been sent to the Marquis of Lansdowne, Secretary of State for War:—

"MY LORD,—The Medical Faculty of the Queen's College, Belfast, respectfully submit for your Lordship's consideration their views on the Army Medical Service, and beg to submit certain changes in this service advocated by the members of the deputations from Trinity College, Dublin, and the Royal College of Surgeons of Ireland, which had the honour of a personal interview with your Lordship on March 9th. The causes that have led to the very marked decrease in the number of candidates from Ireland have engaged our serious attention, more especially as formerly a large number of the students who received their education in the Queen's Colleges entered the Army Medical Service; indeed, fully one-third of the present medical officers in the army holding Irish degrees or diplomas were educated in the Queen's Colleges of Ireland. Our experience regarding the causes that have given rise to the diminution in the numbers of our students now seeking entrance into the Army Medical Department is similar to that stated by the deputations already mentioned. The most important cause of the present unpopularity of this service is undoubtedly the position which the army medical officers hold relative to the other branches of the army, and we would support most strongly the establishment of a Royal Medical Corps. The conditions in the Royal Medical Department are, as a rule, very unfavourable to scientific work by the army medical officers, more especially in the case of those stationed abroad, and we consider that every encouragement and assistance ought to be given, so far as is consistent with the public service, to officers anxious to engage in original research or to keep themselves abreast of the constant advances in medical science. The claims of Ireland and Scotland to representation on the board of examiners for the army medical examinations are so evident and were so ably and fully stated by the deputations from Dublin that it is unnecessary for us to enlarge upon this important reform. Nothing could be more calculated to encourage our best students to enter for the army than the conviction that the board of examiners was thoroughly representative of the various medical institutions in the three Kingdoms, and that it was both unnecessary and useless to spend extra time and money in cramming the special methods or views of any particular school. We believe that the adoption of these changes would remove the serious discontent which at present exists amongst the army medical officers, and would restore the former popularity of the Army Medical Department amongst our students.

Signed on behalf of the medical faculty, by

JOHNSON SYMINGTON, M.D., F.R.C.S. Edin.,
Professor of Anatomy, and Secretary to the Medical Faculty, Queen's College, Belfast.

THE ASHANTI HONOURS.

We subjoin a list of promotions ordered by Her Majesty the Queen as a recognition of the services during the recent Ashanti campaign of the medical officers named:—Surgeon-Colonel William Taylor, M.D., to be Surgeon-Major-General; Surgeon-Major William Owen Wolseley to be Surgeon-Lieutenant-Colonel; Surgeon-Captain Walter Calverley Beevor, M.B., to be Surgeon-Major; and Surgeon-Captain James Maher to be Surgeon-Major. In view of the fact that Her Majesty recently sent a very gracious and gratifying message of thanks to those medical officers who rendered service to His Royal Highness Prince Henry of Battenberg during his illness, and having regard to the successful issue of the campaign from a medical as well as from a military point of view, we should have liked to have seen some honorary rewards also conferred on some of the medical officers. For the success of the undertaking the country is greatly indebted to the Army Medical Service for the wisdom and foresight with which the hygienic and hospital requirements were designed and to the medical officers of the expedition for their very successful arrangements and the great zeal and care with which they fulfilled their duties. The very unhealthy nature of the climate and the disastrous effects on the health of the troops which might have taken place had those arrangements been defective or bad is universally admitted, and it was fitting, therefore, that the excellent services rendered by the Army Medical Staff on this occasion should be recognised. We have to congratulate the above officers on their well-earned promotion.

"Audi alteram partem."

"THE OBJECTS AND LIMITS OF OPERATION FOR CANCER."

To the Editors of THE LANCET.

SIRS,—Without commenting upon the tone or nature of Mr. Watson Cheyne's letter in THE LANCET of March 28th I would first hasten to assure him that it was only lack of opportunity and not disrespect or want of interest that prevented me from attending the Lettsomian Lectures at the Medical Society of London. I am flattered to think he should have noticed my absence from a large and representative audience. I have read Mr. Cheyne's lectures with that close attention which they well merit and which is needful for one who is still a student in these matters to understand what he has written upon a very complicated subject. Differences of opinion are allowable regarding such matters as the "cure" of cancer, and I am glad to know that I do not stand alone in the opinions I expressed. These lectures mark an important period in the surgery of malignant disease. They are valuable as much from their source as from the labour expended in collecting large masses of statistical details for future reference. I still think they would have lost none of their value and interest among those members of the profession who, even at the risk of being called "sententious," are not afraid to think and speak for themselves, if the term "cure" had been used in the more restricted sense indicated.

I am, Sirs, yours truly,

March 30th, 1896. A. MARMADUKE SHEILD.

THE CLINICAL EXAMINATION OF THE BLOOD.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 28th I notice a leading article dealing with the clinical examination of the blood. The subject is one of considerable importance in practical medicine, as it not infrequently happens that most valuable

Digitized by Google

assistance in arriving at a definite diagnosis and in estimating the effect of treatment on the course of certain diseases can be afforded by periodical and systematic examinations of the blood. Till quite recently, however, but little attention has been directed, especially in this country, to this line of investigation, and you have done, therefore, a good service to clinical medicine by calling attention to the trustworthiness or the reverse of the methods commonly employed for such purpose. The remarks as to the unsatisfactory nature of the results obtained in estimating the amount of hæmaglobin in a specimen of blood by means of the hæmaglobinometer I can fully endorse, as doubtless can all who have had much occasion to make use of this instrument or others of a somewhat similar nature. The main difficulties that one has to contend with are ably set out in your leading article, and it was with the hope of obviating some, at any rate, of the possible fallacies there referred to that I wished a few years ago to make trial in work on the blood of Lovibond's tintometer, an instrument then recently introduced for the estimation of colour in various trade processes. The apparatus was kindly placed at my disposal by the inventor, and in conjunction with him I carried out a large number of experiments on blood in health and disease, the results of which convinced me that we have in this instrument an exceedingly accurate means of estimating even minute variations in the hæmaglobin power of the blood. This is so even though the blood be more or less opaque, as is liable to be the case in leucocythæmia, for instance—a condition of things which would render estimations carried out with the hæmaglobinometer altogether valueless. I demonstrated the use of the tintometer for hæmoglobin estimation in the pathological section of the British Medical Association at the Birmingham meeting (in 1891, I believe) and have since then constantly used the instrument for this purpose, and have put on record certain of the results obtained with it. A week or two ago Dr. Oliver showed, at a meeting of the Physiological Society, a simplified form of the instrument which Mr. Lovibond and he had devised, and which will doubtless come into extensive use for clinical work as soon as its superiority over the hæmaglobinometer becomes more fully appreciated. For extremely accurate work, however, and especially if the blood be at all opaque, the original and more bulky instrument is essential, and should, I venture to think, find a place in every physiological laboratory.

I am, Sirs, yours truly,

S. MONOKTON COPEMAN.

Cromwell-crescent, S.W., March 31st, 1896.

PROTEST AGAINST THE INJUSTICE OF THE MEDICAL AUTHORITIES."

To the Editors of THE LANCET.

SIRS,—I shall not regret that you have published the notice-card of mine which was sent you if it serves to reopen a question which will not be allowed to drop again until it is settled once and for all. At the same time I may be permitted to express my surprise that in the comments you were good enough to make on the card in question you should not have felt it necessary to connect it with the general scheme and design of which it was the outcome—a scheme which was contained in a series of interviews on the "Degradation of the Medical Profession," published in the *Paddington Mercury*, and copies of which were duly sent you; for without such connexion and commentary the notice—divorced, as it were, from its context—is calculated to lay me open to misapprehension, while the tone of your comment to those who do not know the circumstances is calculated to do me serious injury. But as you are unwilling to allow me space for the discussion of the various points raised on the interviews I must ask you to allow me to make the necessary personal explanation. The card, as its wording implies, was at once a protest against the injustice of the medical authorities in permitting the touting from door to door of club agents for the benefit of particular medical men and a practical solution to a state of affairs which has become well-nigh intolerable, and arose out of a question of the editor as to whether some scale of fees could not be devised which would be at once within the means of working-class people and at the same time would give the medical man "a living wage." To this I replied that I believed such a tariff was possible, and expressed my willingness to adopt it if other medical men could be found to support me in it. Meanwhile the General Medical Council had refused even its "moral disapprobation" of the club system, and had even gone so far as to say that it existed, not for the protection of the profession against the public, but for the protection of the public against medical men. We were plainly told that we were not to expect any help from them in our battle with the clubs and were left to fight the matter out as best we may. The cards accordingly were issued after consultation with, and by the approval of, a number of other local practitioners not connected with the clubs, as an experiment to see how far the battle with the clubs could be successfully fought in this particular locality by a scale of fees such as I propose, I, as the oldest practitioner, undertaking to issue the cards in my own name and on my own responsibility. As regards my own *bona fides* in the matter, I may say that the cards were sent beforehand to the different medical journals, together with copies of the interviews in the *Paddington Mercury*, inviting comments on my scheme, and intimating that I would report progress as to the results of the experiment. That it was from no jealousy of the club medical men that I issued the cards is evident from this, that not only had I the first refusal of the leading clubs when they started here some years ago, but within the last few weeks I have had again the offer of one of the largest of them, and have again refused on the ground stated in the interviews, viz., that it is impossible to do justice either to oneself or the patient unless the club rate is *doubled*—that is to say, is made 2*d*. a week instead of 1*d*., as at present. And, lastly, as I was by my new tariff to receive in future only one-half of what I had been receiving from all the old patients who fell within the wage limit laid down by me the experiment, as, indeed, it has so far proved, was a very doubtful one so far as any increase of my own income is concerned. It is too soon of course for a final judgment, but my own feeling from all I have learned is that the clubs are so deeply intrenched that nothing can prevail against them except a scale of fees on which it is quite impossible to live.

I am, Sirs, yours faithfully,

JOHN BEATTIE CROZIER.

Elgin-avenue, W., March 24th, 1896.

"THE QUESTION OF MEDICAL DEFENCE."

To the Editors of THE LANCET.

SIRS,—In reply to Mr. Horsley's letter which appeared in THE LANCET of March 28th we beg leave to say that we have nothing to add to what we have already stated on this subject, and we must decline to be drawn into the discussion of any such irrelevant matters as the alleged interference of solicitors. This is, so far as we are concerned, our last remark on this subject. Thanking you for your courtesy,

We are, Sirs, yours faithfully,

G. A. HERON,
W. BRUCE CLARKE, } Delegates of the London and Counties Medical Protection Society.

March 31st, 1896.

To the Editors of THE LANCET.

SIRS,—Your article on the report of the Medical Defence Union, Limited, raises an important point—namely, the expediency of the absorption of the Union by the British Medical Association. This absorption appears to me to be desirable solely on the ground of economy. Multiplicity of organisations—if they are to serve any useful purpose at all—implies waste of money and waste of energy, and one powerful organisation will produce far better results than any number of smaller ones. Then another point arises: Is it not probable that, if there ever is established a powerful representative authority, the present inordinate number of individual cases with which defence associations are concerned will very materially lessen. The great evils which at present are with us owe their origin in a great measure to the want of representative institutions. The corporations aim at keeping the great mass of the profession in *statu pupillari* from the cradle to the grave: so far they have had their success. However much we look back with pleasure on our school and college life, very few of us would wish to have the schoolmaster or the college don in perpetual dominion over us. That condition is, however, to a very large extent that which obtains in our profession. Lecture-room methods are very well in their proper place, but when introduced into everyday life are not likely to promote general harmony. Unless

Digitized by Google

the majority of the members of the profession now combine to make the British Medical Association the great and powerful representative authority which it should be I see no chance of the profession exerting its full force either in the way of maintaining internal discipline or as a political factor.

The corporations have quite failed to recognise the fact that circumstances have changed and with a tenacity worthy of a better cause they cling to methods quite a century old. Under these circumstances the best policy before the profession will be found to be to say to the corporations, "by all means keep to your old world methods; we will make a corporation in which the meanest of its members will have a voice and an interest." Your article raises a second point, that of the position of a member of the General Medical Council with reference to his membership of such an association. Surely at the present time it has been shown pretty conclusively that corporation representatives sit on that Council, not to consider the interests of the profession as a whole, but the interests of the particular corporation which they represent. Why then should not members belonging to a representative body sit on such a Council? Your remarks on this head—if proof were needed at all—prove the necessity of the profession being considered as a whole and not as a mere collection of cliques, each one arrogating to itself superiority. If the corporations did not refuse corporate existence to the bulk of those who are connected with them the matter would be upon a different footing. As it is, absolutely unrepresentative of the profession as a whole or even a part, these bodies in every way promote disunion, which a united representative authority would discourage.

I am, Sirs, your obedient servant,

Hatfield, March 22nd, 1896. LOVELL DRAGE.

ACCIDENTAL RASHES IN TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—The cases of accidental rashes occurring in typhoid fever simulating scarlet fever, published in THE LANCET of March 21st, are of considerable interest, especially, I take it, in connexion with the question of isolation. Scarlatiniform rashes during typhoid fever have come under my notice twice during two epidemics, but the following case of erythema scarlatiniform occurring during varicella appears to me unusual.

The case was that of a child aged three years who had been ailing six days; the patient had varicella eruption in various stages on the scalp, face, neck, chest, and abdomen; the symptoms were very slight. Two other children in the house were also suffering from it. On the seventh day a punctiform scarlet erythematous rash appeared over the whole of both upper and lower extremities, the temperature rose to 101° F., and the pulse to 140, the throat was normal and the tongue clean; there was conjunctivitis of the right eye. On the eighth day the rash was the same, the tongue was slightly coated with white fur, the temperature was 98·6°, the pulse 130, and the throat normal. On the ninth day the rash had quite faded, but fresh vesicles appeared on the abdomen. On the tenth day the tongue was quite clean, the conjunctivitis cleared up, and the patient was apparently well. At no time was there any albumin in the urine. No desquamation followed; the patient was under strict supervision for three weeks after. There was no scarlet fever in the neighbourhood at the time. Erythema in its many varieties is not uncommon in the district. No cause could be connected with the case with regard to medicine or diet. I have no doubt many practitioners have observed similar cases, and know how careful they had to be not to give a too hurried diagnosis.

I remain, Sirs, yours faithfully,

Newark-on-Trent, March 25th, 1896. ERNEST RINGROSE.

THE ADMINISTRATION OF PENTAL.

To the Editors of THE LANCET.

SIRS,—I trust that I may have misinterpreted Dr. Prince Stallard's paper and the subsequent discussion as reported in the syllabus of the proceedings of the Society of Anæsthetists in THE LANCET of March 14th. Dr. Stallard reported 150 cases of the administration of pental with one death; Dr. Dudley Buxton compared the reported cases of Gurlt (600, with three deaths) and Snow (238, with two deaths); in all, 988 cases with six deaths. Unless I have misread these figures we have the appalling mortality of one person out of every 164 to whom, in the practice of these anæsthetists, pental was administered to save a minute's pain. (The average duration of unconsciousness was in Dr. Stallard's cases seventy-six seconds.) The president is reported to have said that he was delighted to see members of the society pursuing their investigations into various drugs likely to become good anæsthetics. It is surely time that some old-fashioned practitioner like myself, who believes that the first object of a medical man is to preserve life, should protest against the use of so dangerous an anæsthetic, the advantages of which are stated to be: (1) that the patients recover quickly (if they recover at all); (2) no coughing, struggling, or dislike to the drug; (3) small amount required; (4) absence of after effects; (5) longer anæsthesia than nitrous oxide gas; and (6) simple apparatus. Besides five other stated disadvantages we have the fact that it is at least 100 times more fatal than other anæsthetics. I have practised surgery for more than thirty years and during that time have either myself administered or been responsible for the administration of anæsthetics in several thousand cases, and, happily, I have only seen one death (from chloroform in a prolonged abdominal operation). I cannot but compare my own experience and that of others in the use of the more ordinary anæsthetics with these reported cases of the results obtained from pental, and once more, although no specialist on the subject, protest emphatically against any further sacrifice of life from its use.

I am, Sirs, yours faithfully,

March 27th, 1896. THOMAS JAMES WALKER, M.D. Lond.

MIDWIVES' REGISTRATION BILL.

To the Editors of THE LANCET.

SIRS,—The second reading of the Midwives Bill is fixed for May 6th. In the meantime we wish to urge that the following action be taken immediately by each practitioner: 1. He should at once write to his Member of Parliament asking him to strongly oppose the second reading of the Bill, enclosing a copy of the "Reasons" against registration which may be obtained on application to the honorary secretary at the undermentioned address. 2. He should call at his earliest on the local political secretary of his Parliamentary division and ask him to communicate with his Member of Parliament his own feeling and that of local practitioners. 3. He should join at his earliest his local political association or club and ask its secretary and leading workers to write to his Member of Parliament, giving him copies of the "Reasons." 4. He should call a meeting of local practitioners, pass a resolution against the Bill, send a copy to their Members of Parliament, and ask them if they will receive a deputation of local practitioners. The same meeting should appoint a deputation and provide for the payment of travelling expenses. The local political secretary would arrange for it with their Members of Parliament.

We do not place much faith in the passing of mere abstract and academic resolutions or the signing of petitions. If the majority of practitioners in each Parliamentary division will write at once to their Members of Parliament asking them to oppose the Bill, sending them a copy of the "Reasons" signed by local practitioners, obtain the help of their local political secretary and of their local political and lay friends, these practical methods will give the best results. A list of Members of Parliament will be found in *Whitaker's Almanac*, pp. 135-145, and the address "House of Commons, London," will find them. As it is necessary that all opposition be organised in London, will practitioners please let the honorary secretary know the replies from their Members of Parliament? Funds are required to successfully oppose the Bill; we therefore propose that a "Midwives Bill Opposition Fund" be now formed. Copies of the "Reasons," pamphlets, and other information may be obtained from the honorary secretary.

We are, Sirs, yours faithfully,

C. CAMPBELL, W. W. HUGHES,
L. DRAGE, L. KIDD,
J. M. DOLAN, LAWSON TAIT,
G. C. SHUTTLEWORTH, R. R. RENTOUL (Hon. Sec.).

78, Hartington-road, Liverpool, March 28th, 1896.

"DEATH UNDER CHLOROFORM AT A DENTIST'S ROOMS."

To the Editors of THE LANCET.

SIRS,—Mr. Wardill's letter upon this subject in THE LANCET of March 21st raises many important questions, upon one or two of which I should like to be permitted to make a few remarks. I quite agree with those who think that nitrous oxide should be the main anæsthetising agent in all tooth-extraction work—nitrous oxide alone in the majority of instances and etherised nitrous oxide in cases of multiple extractions. The extent to which these agents will suffice for dental work is capable of numerical proof. For example, I have records in my own private note books for the past year of seventy-nine cases in which from four to six teeth were extracted, and of thirteen in which seven teeth and upwards were removed, including one case of fourteen extractions, one of thirteen, two of ten, and two of eleven. These figures refer, of course, to single sittings; no hospital cases are included in these records; and in all nitrous oxide was the main anæsthetising agent. With such figures as these before one it is difficult to say that chloroform should be preferred in any case. For surgical reasons I am always inclined myself to doubt whether it is judicious to advise the extraction of large numbers of teeth at a single sitting. But assuming that such a proceeding is absolutely imperative in some circumstances I would urge that these cases should be treated, not so much as tooth extractions pure and simple, but rather as operations about the mouth, and I would submit that for operations about the mouth the "dentist's rooms" are certainly not the proper place. Such operations should be performed either at the patient's home or in some institution where proper nursing is available, and, in fact, the ordinary operative routine, as distinguished from the routine of simple tooth extraction, should be adopted in every instance. Until this plan is adopted I fear that we shall continue to hear of accidents such as have been recently reported. I believe that I am right in saying that those who are responsible for the teaching of anæsthetics in our medical schools are absolutely unanimous in condemning the administration of chloroform in the dental chair; in fact, some go so far as to teach that the proceeding is not justifiable under any circumstances. If the matter were put to the patient in this way it would be seldom, I think, that he would hesitate to adopt the more cautious plan of two or three sittings, or that he would grudge the slight extra expense which might be involved.—I am, Sirs, yours faithfully,

J. F. W. SILK,
Anæsthetist and Instructor in Anæsthetics at King's College Hospital; Anæsthetist to Guy's Hospital Dental School.
Weymouth-street, W.

"THE DUTIES OF DIVISIONAL SURGEONS IN CASES OF INFECTIOUS DISEASES."

To the Editors of THE LANCET.

SIRS,—In reply to the letter published in THE LANCET of March 21st by Dr. Thyne, as I am the divisional surgeon referred to in that letter I consider it only right to give you my explanation. The charges made I admit are quite correct as stated in his letter, but that gentleman omits to tell you that he has frequently within the last year done exactly the same to patients of mine; and that he takes every opportunity he gets to make the duties of divisional surgeon as disagreeable as he can. I have been in practice in Barnet twenty years; during the whole of that time the families of the police were attended privately by me and the other medical men resident in the town until within the last three years, when Dr. Thyne offered his services at the following rates: woman and child, 1½*d.* per week; a whole family, no matter how many children, 2½*d.* per week. For this sum he contracted to attend all illnesses, including fractures, dislocations, operations, and infectious diseases, and for this splendid remuneration were included the families of divisional inspectors, inspectors, station sergeants, sergeants, and constables, whose weekly wages are £4, £3, £2 15*s.*, £2 8*s.*, £1 14*s.*, £1 12*s.*, £1 10*s.*, and £1 7*s.* In this town there is only one other society, the Mutual Aid Society, who provide medical attendance for the families of the working class. They pay their medical officer, Dr. Mercer, 6*d.* per week for a whole family, or 2*s.* per month, against Dr. Thyne's 9*d.* per month. I ask you, Sirs, is he acting fairly towards his brother practitioners? Is it not degrading to the profession of medicine? Perhaps your Commissioner will include this case in his essays on the "Battle of the Clubs."

I am, Sirs, yours faithfully,

W. J. HARNETT, F.R.C.P. Edin.,
Divisional Surgeon, Barnet.
Belvedere House, Barnet, March 24th, 1896.

"THE SCHOTT TREATMENT OF HEART DISEASE."

To the Editors of THE LANCET.

SIRS,—Dr. Leith's paper, published in THE LANCET of March 21st and 28th, is one of the few serious attempts to place Schott's system on a scientific basis, and as such deserves critical study. With most of Dr. Leith's conclusions I entirely agree, but there are some important points which he appears to me to miss, and a few of these I propose to briefly touch upon. 1. Dr. Leith admits that the respiratory movements are amplified by both the baths and exercises; but he does not think that this amplification governs the circulation, arguing that the accelerating influence of the deep inspirations is counterbalanced by the retarding effect of the expirations. It must, however, be remembered that it is only when expiration is forcible, or when it proceeds beyond the ordinary limit, when, in fact, it is "extraordinary," that it appreciably retards the circulation; and in the case before us it is doubtful whether it is either forcible or extraordinary, it being essentially a passive recoil from a state of amplified inspiration. 2. I would suggest that the retraction of the abdomen and ascent of the diaphragm which take place in the bath are only in part, if they are at all, due to the pressure of the super-incumbent water. The effect of cold when applied to the body is to cause expansion of the bony thorax and to excite costal respirations. Witness the effect of dashing cold water on the back—a deep sigh results, and a sigh is essentially effected by means of a costal respiration. This costal expansion, together with the contraction of the abdominal muscles which results from the cold, causes the flattening of the abdomen observed in the bath. 3. The effect of this latter is to increase the intra-abdominal tension, and the inferior cava and splanchnic veins being thus compressed the return of blood to the right heart is impeded, so that this chamber has an opportunity of disgorging itself of any excess of blood it may contain, a process that is favoured by the deepened inspirations. 4. I have said that cold tends to increase the tonic contraction of the muscles. One is conscious of a widespread semi-voluntary contraction of the muscles when cold is applied to the body, the individual bracing himself up, as it were, to resist the cold. Now the effect of this increased muscular tone is to attract blood to the muscular system and to hinder the venous outflow from it; and this further tends to diminish the input of the right heart. 5. Resisted movements have a similar effect. Dr. Leith quotes an opinion of Dr. J. F. H. Broadbent—one he himself is inclined to share—to the effect that the resisted movements "press upon the veins and favour the return of the venous blood to the heart." This is the very thing I believe they do not do. Writers on the Schott treatment have entirely lost sight of the important fact that a resisted movement implies a widespread tonic contraction of the muscles. When such a movement is made, not only are the muscles especially engaged in it tonically contracted, but there is an increased tonic contraction of numerous others in order to preserve the equilibrium (for be it observed these movements are nearly always performed while the patient is standing). In short, almost the whole muscular system is thrown into a state of tonic contraction. The effect of this, like that of cold, is to attract blood to the muscles and at the same time to diminish the venous outflow from them, the flaccid veins being *continually* compressed; intra-abdominal tension is, moreover, raised by the tonic contraction of the abdominal muscles, and the flow in the splanchnic veins and inferior cava thus impeded. 6. The baths increase the mean arterial resistance and thus tend to limit the arterial output, and I am not sure that widespread tonic contractions have not the same effect. Be this as it may, I am convinced that the Schott system does not benefit, as many suppose, by diminishing peripheral resistance, but rather by increasing it. There can be no doubt, as Sir William Broadbent has so ably

Digitized by Google

insisted, that a great deal of heart disease is causally associated with prolonged high tension, and that a high peripheral resistance is an essential factor in initiating dilatation of the left ventricle. Nevertheless, it is only in a limited number of cases of heart failure that we are called upon to reduce peripheral resistance, and then only as a temporary measure. In the worst cases radial tension is generally low, and the meagre stream of blood escapes all too readily into the already overgorged veins. In such cases we seek to increase rather than to diminish resistance, and the good effects of digitalis are in no small measure referable to its constricting influence on the arterioles. Sometimes, indeed, vaso-motor constriction occurs as part of the general scheme of compensation, as happens more particularly in mitral obstruction and in obstruction originating in the pulmonary circuit. 7. I have argued that the baths and resisted movements tend to limit the flow into the right heart; but how, it may be asked, can this conclusion be reconciled with the undoubted fact that the entire circulation is accelerated by their means? The answer is that the flow into the right heart is only relatively diminished — i.e., when considered in relation to the increased cardiac activity. There is no doubt that both the baths and movements stimulate the right heart (how we need not stop to consider), so that, while on the one hand blood is prevented from flowing too readily out of the arterial system, the supply to the veins being thereby limited, and while on the other hand the flow from the veins into the right side of the heart is impeded, this organ is incited to aspirate and urge on the blood with increased force, while at the same time the deepened inspirations favour the pulmonary flow. And here, Sirs, I must end, though I have only been able to touch upon the fringe of this important subject. In conclusion I beg to express my deep obligation to Dr. Leith for his valuable paper. I am, Sirs, faithfully yours,

Devonshire-street, W., March 28th, 1896. HARRY CAMPBELL.

"AN INQUIRY INTO THE PHYSIOLOGY OF THE ACTION OF THERMAL SALINE BATHS AND RESISTANCE EXERCISES IN THE TREATMENT OF CHRONIC HEART DISEASE."

To the Editors of THE LANCET.

SIRS,—The following references have appeared since the date of delivery of this paper and while it was in the hands of your printers:—

53. Herschell: Critical Remarks upon the Nauheim Treatment of Heart Disease, THE LANCET, Feb. 15th, 1896, p. 413. He failed to get any favourable results in his cases and entirely condemns the system. 54. Brown (Ralph): The Nauheim Treatment of Heart Disease (a letter). THE LANCET, Feb. 29th, 1896, p. 585. He emphasises the influence of CO_2 and its absorption by the lungs. 55. Bezly Thorne: Notes on Certain Changes in the Cardio-vascular System which are Induced by Treatment according to the Schott Methods, Brit. Med. Jour., March 14th, 1896, p. 653. He distinguishes an oval, bipartite, and conoid form of dilated heart as made out by auscultatory percussion, a method which is, in my opinion, quite untrustworthy, and has given him illusory results. 56. Kingscote: Fifteen Months' Practice of the Schott Methods for the Treatment of Chronic Affections of the Heart, THE LANCET, March 21st, 1896, p. 761. He gives seven cases, but we fail to follow him in his *rationale*. 57. Bezly Thorne: Self-poisoning in Heart Disease and its Relation to the Schott Method of Treatment, THE LANCET, March 21st, 1896, p. 755. 58. Bowles: The Nauheim and Schott Treatment of Diseases of the Heart, a paper read before the Harveian Society of London, March 19th, 1896. He supported the methods *in toto* and gave four corroborative cases.

I am, Sirs, yours faithfully,

Edinburgh, March 24th, 1896. R. F. C. LEITH.

"RUPTURE OF THE TERMINAL EXPANSION OF THE EXTENSOR COMMUNIS DIGITORUM."

To the Editors of the THE LANCET.

SIRS,—Dr. F. G. Wallace's case of rupture of the terminal expansion of the extensor communis digitorum[1] reminded me of a similar case which came under my care on July 16th, 1895. The patient, a man aged fifty-five years, of a delicate constitution, while trying to lift a pillow weighing about 500 drachms, felt something give way with a snap in his left ring finger, but felt no pain. On looking at it he was startled to see the third phalanx flexed almost at right angles to the second. I saw him immediately after. The phalanx could be easily pushed straight, but would soon drop to its former position if left alone. On the lower third of the dorsum of the second phalanx a small, tender swelling could be seen, which was undoubtedly the point where the ruptured end of the tendon had been drawn. The groove corresponding to the second phalangeal joint could be felt more distinctly in this finger than in the others, especially when the third phalanx was held in a position of semi-flexion, owing to the rupture of the expansion of the tendon which forms the posterior ligament of the joint. I soon put the whole finger, completely distended, in plaster of Paris, in order to put the joint in a sure state of complete rest. In two weeks the plaster was removed and the joint was found to be better; some movement could be seen in it. I put it again in plaster for fifteen days more, at the end of which I found the joint quite movable, but not easily and freely, the swelling at the dorsum of the second phalanx was smaller and the tenderness had by this time disappeared. For fear of having the tendon ruptured again I put it for fifteen days more in plaster, and when this was removed the joint was seen to be strongly and freely movable, the swelling almost gone, and the man is now as well as ever.

I am, Sirs, yours truly,

Alexandria, March 10th, 1896. S. F. SHAMOUN, M.D.

[1] THE LANCET, Feb. 29th, 1896.

CONFIDANT OR INFORMER?

To the Editors of THE LANCET.

SIRS,—In a recent libel case Sir John Williams is reported to have said that "a medical man is obliged to inform the Public Prosecutor of any crime which has been committed or is intended to be committed." I do not know what significance Sir John Williams attaches to the term crime, but I take it that he uses it not in the literal sense of a matter for inquiry, but in the conventional sense of a violation of the law. Attempted suicide is "a crime under the law," to employ an expression used by Mr. Justice Hawkins, and I should like to ask if it is held that a medical man who is called on to attend a patient who has taken poison admittedly for suicidal purposes and who recovers is bound to communicate with the police. Speaking from personal experience, I may say that I have attended many patients under these circumstances and that I have never given information. If the patient dies there is an inquest and the matter settles itself, but to go away from the patient's bedside after saving his life and denounce him to the police seems to me to be a hateful taste and to be contrary to all principles of morality. Rather than do so I would take my chance of being charged as accessory after the fact, for I am sure no jury would convict under the circumstances. In spite of the respect which, as an old pupil, I naturally entertain for the high position of Sir John Williams, I am bound to say that I do not appreciate this new code of ethics, and I am sure that it will be a bad day for the profession when the public cease to believe that their secrets are held inviolate by their medical advisers.

I am, Sirs, yours faithfully,

WILLIAM MURRELL.

Welbeck-street, Cavendish-square, W., March 27th, 1896.

THE TWELFTH INTERNATIONAL MEDICAL CONGRESS AT MOSCOW.

To the Editors of THE LANCET.

SIRS,—I have received a further letter from Professor Crisman, the general secretary of the next International Congress, in which he tells me that the question of languages is to be reconsidered by the executive committee, and that in all probability the English language will be admitted to equal rights with German, Russian and French. The letter continues: "This will be done because it has become clear that the exclusion of the English language would not be well received by our English colleagues, and the committee do not consider themselves justified in insisting on their first decision if the general opinion of our English colleagues is clearly against it. You may rest assured that the committee, in discussing this question and coming to their first decision, were guided solely by considerations of what would be of

Digitized by Google

advantage to the Congress, and were far from having in view the national aspect of the matter."

I am, Sirs, yours faithfully,
YOUR ST. PETERSBURG CORRESPONDENT.

"ASSISTANTS."

To the Editors of THE LANCET.

SIRS,—I have read the letter in THE LANCET of March 21st signed a "Sorely-tried Principal," and with your permission I will state my opinion of principals in general, backed by an experience extending over three years as assistant in various practices. The average general practitioner holding club appointments, and, therefore, requiring a qualified assistant, is lamentably ignorant, not only in the use of drugs, but in all recent hospital work, and as a rule treats his assistant little better than a horse, endeavouring to get as much work out of him as possible and at the same time paying him a small salary which many shop-boys would despise. We assistants as a class are in a disgraceful position, being merely paid servants of our employers, and it is quite time that we should endeavour to combine and better our status. Whenever I read in the "Battle of the Clubs" medical aid societies sweating their medical officer it occurs to me that the principal sweats his assistant ten times worse. The public in general are disposed to blame an assistant if he leaves his principal, but in my experience life frequently with the latter is little short of a mild hell, and that is saying a good deal. I am sorry to say that assistants are a necessary evil as long as club practice exists. We have the remedy in our own hands—that is, proper combination for our own mutual interests. Apologising for trespassing on your valuable space,

I am, Sirs, yours truly,
March 24th, 1896. A SORELY-TRIED ASSISTANT.

THE BATTLE OF THE CLUBS.—XXVI.[1]

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 805.)

NOTTINGHAM: THE LONDON AND MANCHESTER INDUSTRIAL ASSURANCE COMPANY, LIMITED.—THE PUBLIC-HOUSE MEDICAL AID CLUBS.

ALTHOUGH there are a great many organisations for providing medical aid in Nottingham it is principally against the London and Manchester Industrial Assurance Company, Limited, that the members of the profession in this town have taken up arms. Judging from the experience acquired in other towns this special feature of the struggle at Nottingham seems to me somewhat surprising. I am anxious not to dogmatise; I do not pretend to know more than what has come under my personal observation; I simply record facts as they happen to present themselves to me. Now it may be a mere coincidence—perhaps in other towns I may collect evidence of an opposite character—but I feel bound to record as a matter of fact that till the day I reached Nottingham I never came across any practitioner who complained of the action of what is familiarly called the "London and Manchester." On the contrary, many a practitioner has, while complaining bitterly of different medical aid associations, ended by saying that the London and Manchester Company was "all right." The system, doubtless, was "all wrong," but in actual practice there was nothing particular to complain about so far as the London and Manchester Company was concerned. Perhaps in Nottingham the agents of this company have not displayed their usual tact. The trouble, I am told, began in the following manner. A well-known practitioner was attending a patient whose annual bill amounted to a sum of £10. The patient, however, joined the London and Manchester, and then the practitioner discovered that henceforth he could only hope to receive 4*s.* where he had formerly been paid £10. Seeing that the patient was a man of means, it was very natural that his medical attendant should feel somewhat wrathful and he communicated his resentment to the Nottingham Medico-Chirurgical Society. The matter was taken up and this was the commencement of the discussions that have led to the formation of a medical union, as already fully described. It was now found that the agents of the London and Manchester Industrial Assurance Company, Limited, were distributing all over the town a circular bearing the name and address of twenty Nottingham practitioners, several of whom are men who hold the highest position in the town. On one side of this handbill or circular it is stated that the company was established in 1869, is incorporated under Act of Parliament, with authorised capital of £100,000. Then there are tables divided into seven columns, each column relating to seven different rates of payment, which vary from 2½*d.* to 7½*d.* per week. Thus, in the first column, one reads that a person who will be eleven years old on his next birth-day can insure his life for the amount of £10, and also receive medical attendance and medicine during illness, for the payment of 2½*d.* weekly. Each year the sum insured is smaller. At twenty years of age it is £8 5*s.*; at thirty years, £6; at from sixty-five to seventy years only £1. As the danger of death increases the amount insured is decreased: no difference, however, is made as the danger of illness increases. At most the medical officer receives a penny a week, whether the subscriber be young or old, healthy or feeble. It is even expressly stated on the circular that no medical examination is required if the sum insured is under £20, unless the subscriber is more than fifty years old. Then there is a second table dealing with the infantile department. Here are set forth the sums payable at death in exchange for a subscription of 2½*d.* per week, which includes medical attendance and medicine during illness. Thus if a child under one year old is insured and dies after three calendar months, £1 10*s.* is paid; if after one year, £2 15*s.*; and after ten years, £10. On the other side of the circular is the following announcement:—

"The distinguishing feature of this company is, that it not only enables persons to assure for a sum payable at death, but also to secure in case of illness the best medical attendance (at their own homes whenever necessary), medicine, and advice, the two benefits being combined for the small sum of 2½*d.* per week. Over 1000 duly qualified medical gentlemen are attached to the company throughout the country, and members are transferred from one district to another free of charge. Members are allowed to choose any doctor on the company's staff, no pressure being put upon them to have any particular one. There are no entrance fees, fines, or levies of any description."

Then examples are given of the working of the insurance, and in each case stress is laid on the advantage of the medical aid. Thus in the margin of the circular is printed:—

"Example.—A person forty years of age next birthday at time of entry can secure the best medical attendance and medicine in illness and £4 payable at death for a premium of 2½*d.* weekly. If a premium of 3½*d.* weekly be paid the sum payable at death is £9."

Then we are informed that no better proof of the success of the company can be given than the fact that 141,135 new policies were issued during the past financial year. Following on the purely business statements that are printed on this little circular or handbill—which can be distributed anywhere, slipped under doors, or dropped into letter-boxes—are the names, addresses, and qualifications of twenty Nottingham practitioners. The same circular is used in other towns, the names and addresses of the medical officers alone being altered. It is this advertising of medical men that has especially vexed the profession at Nottingham, and several of the medical officers in the service of this company are most anxious to have their names erased from this circular, but rightly conceive

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Aug. 24th, 1895, Brussels; (2) Aug. 31st, 1895, Brussels; (3) Sept. 21st, 1895, Portsmouth; (4) Sept. 28th, 1895, Portsmouth; (5) Oct. 5th, 1895, Eastbourne; (6) Oct. 12th, 1895, Lincoln; (7) Oct. 26th, 1895, Lincoln; (8) Nov. 2nd, 1895, Grimsby; (9) Nov. 9th, 1895, Bexhill-on-Sea; (10) Nov. 16th, 1895, Hull; (11) Nov. 23rd, 1895, Hull; (12) Dec. 7th, 1895, York; (13) Dec. 14th, 1895, Northampton; (14) Dec. 21st, 1895, Fermanagh Medico-Ethical Association; (15) Dec. 28th, 1895, Northampton; (16) Jan. 4th, 1896, Birmingham; (17) Jan. 18th, 1896, Birmingham; (18) Jan. 25th, 1896, Club Practices in Rural and Mining Districts; (19) Feb. 1st, 1896, The Formation of a Provident Medical Association at Folkestone; (20) Feb. 8th, 1896, The Manchester Medical Guild and Medical Aid Associations; (21) Feb. 15th, 1896, The Leicester and Leicestershire Provident Dispensary; (22) Feb. 22nd, 1896, The Organisation of the Profession at Leicester; (23) March 7th, 1896, Loughborough: Local Efforts Defeated by Consultants from Neighbouring Towns; (24) March 14th, 1896, Medical Aid Societies in Small Heath; Medical Clubs at Stockport; (25) March 21st, 1896, General Meeting of the Profession and the Formation of a Union at Nottingham.

Digitized by Google

that more good will be done by organising first and then resigning collectively.

Apart from this question of advertising medical men, which is not peculiar to the London and Manchester Company but is practised by all insurance companies, I was anxious to ascertain what were the special complaints against this particular company. After some search I discovered a practitioner who very kindly gave me a full account of his experiences. Several years ago he established himself in a growing district on the outskirts of Nottingham. Houses were then in the course of construction, many streets being barely laid out and as yet possessing no houses. When he had been here a little more than a year and had already acquired some popularity among the neighbours he was approached by an agent of the London and Manchester Company, who wanted to engage his services as one of the medical officers of the company. Having acquired some experience of this sort of work in another town the medical man in question at first refused this offer. The agent of the company urged that it would make him known, but my informant shrewdly suspected that the boot was on the other foot; that he was known and the company was not known, and that the insurance agent was anxious to avail himself of the popularity which the practitioner had acquired. However, the agent went on to explain that the insurance company did business with very poor working people and persons who had large families. When ill these people would certainly send for my informant; he would have to attend to them, but he would not be paid for his services. He might send in his bill, but this class of patients were too poor to pay. On the other hand they might be persuaded to pay a small insurance premium, and that would be better than nothing. This, in any case, was a well-founded argument, for with a certain class of persons the only prospect of payment is by weekly instalments. Thereupon the medical practitioner in question consented to become one of the medical officers of the London and Manchester Company, it being understood that the agent would only enrol a small number of subscribers and these were to be recruited from among the class of very poor people who could not be expected to pay in any other way. To my informant's surprise he soon found that the number of patients went up by leaps and bounds. The agent was most active. He even persuaded out-patients of the hospitals to join. This naturally increased the proportion of patients who were subscribers and unduly augmented the practitioner's work, for, as stated above, there is no medical examination for persons who insure for less than £20.

In a little while it became apparent that where there was a family of several children it was always the unhealthy child whose life was insured, while the healthy children were not insured, thus entailing on the medical officer the maximum amount of work for the minimum amount of pay. On one occasion a woman who was in a dying condition was allowed to insure. The medical officer protested, but the agent answered that it did not matter as the woman would surely die before she had paid enough to be in full benefit. The medical officer thereupon retorted he would send in his bill for full medical fees to the company as they had called him in. If they intended to shirk their responsibilities he would do so also. The result was that the company on the death of the patient paid a much larger sum than they would otherwise have done. It will be seen that no thought is given as to the medical officer's interests. It does not matter how much work he has to do or money to spend in the providing of drugs. Soon it became evident that the agent was not working exclusively among the poor who could not be expected to pay medical fees. On the contrary, he had enrolled well-to-do tradesmen and solicitors' clerks, and was beginning to neglect the streets where the poor people lived. When the medical officer complained the agent replied, "Oh, we can get better people in than that." Looking at the matter from the money-making insurance point of view, the agent failed to realise that he had by that one sentence aptly described the irreconcilable character of the interests of his company and those of the medical profession. The agent was proud of the fact that he could afford to neglect the poorer people, forgetting that the medical officer had consented to serve on the condition that he should be called upon to attend only the poor, and that it was essential the "better people" should not be insured against sickness at rates only applicable to the very poor. Finally my informant found that the agent followed him about and noted the address of his private patients, called upon them, and persuaded them to insure their lives. They would then be attended by their own medical man just as formerly, but would only have to pay a penny per week instead of 2*s*. 6*d*. or more per visit. Many persons were thus persuaded to join the insurance company, and the medical officer lost several of his paying patients. This brought matters to a climax and my informant wanted to resign, but the other medical practitioners of the neighbourhood persuaded him not to do so, on the ground that the company would surely bring down a new practitioner and that there were already medical men enough in the town. He then said that instead of having 600 to 700 subscribers to the London and Manchester Company on his books he would only take 200, so as to have only the poor. But this did not work well and my informant finally resigned. Thereupon the superintendent of the company came down to see if he could not arrange matters. He confessed that the company would lose a good deal if the medical officer persisted in resigning, and at a recent meeting the directors of the company had stated that, thanks to the work done by the medical men, they were able to declare a good dividend. This very clearly shows that medical men are utilised by financial companies for speculative purposes and that it is all a matter of business and not a question of philanthropy.

My informant, in spite of all the persuasion brought to bear, persisted in resigning, and the company consequently wrote him a letter to the effect that they must make arrangements "to take over the practice." This sentence will be duly appreciated. After successfully pursuing an expensive course of studies a medical man establishes himself in a district, he not only creates for himself a good practice, but he enables an insurance company to effect a great many insurances; and then, when he no longer cares to work for this company, they coolly write and inform him that they must make arrangements to take over his practice. Nor is this an empty threat; it is too often very effectively carried out. In the present instance the company, it is true, were not very successful. They brought a medical man down, and it was thought that he would settle in the district, but it did not seem to suit him and he has gone away. Then they persuaded two young medical men who live in Nottingham and at some distance to open small surgeries in the district in question, where they attend now and then. But this is not very successful, and my informant is now getting back many of the patients he had lost.

There are a number of other insurance companies in Nottingham and many clubs and friendly societies. The usual complaints are made about these institutions. They enrol many comparatively wealthy people, and one of the mayors of Nottingham was a member of a friendly society and did not scruple to claim medical aid at club rates, notwithstanding the high position he occupied. But the worst feature is the existence at Nottingham, as at Grimsby, of public-house slate clubs. The only difference is that they have adopted a better title. The call themselves "sick and annual clubs." This certainly sounds a little better, but it is not flattering to see hung up over a public-house bar an announcement that "A Sick and Annual is held here," followed by the name and address of the medical man whose services have been secured. Some publichouses go to the extent of having the announcement engraved on a brass plate; perhaps this is thought more professional. The system is the same, the subscription usually being 6*d*. per week. A sick allowance of 5*s*. for six weeks is often made, and in all cases medical attendance and medicines are provided. Whatever money remains in hand at Christmas is evenly divided among the subscribers by the publican. The payment made by the publican to the medical man seems, however, somewhat higher than at Grimsby. Not long ago a publican asked a Nottingham practitioner how much he would take to attend the club which the publican was about to establish. The price mentioned was 4*s*. The publican subsequently called on another practitioner, who, hearing that 4*s*. had been demanded, offered to take the club for 3*s*. 6*d*. The publican then called on a third medical man, with whom he closed the bargain for 3*s*. 4½*d*. While medical men thus undersell each other for the honour of being medical officers to a public-house club, it is rather difficult to uphold the honour and dignity of the profession. A well-known Nottingham practitioner related to me that he had very recently been asked to become medical officer of one of these public-house clubs. The publican explained that he had enrolled 60 members and wanted them to be admitted without medical examination. This might be considered as

Digitized by Google

a sort of privilege given to the founders of the association, but he had 120 more persons who would in all probability join, and these might be medically examined before admission. The publican urged that it would be a very good club, that all the neighbouring shopkeepers had joined, and that if the medical man did not accept the position he would lose many of his patients. Indeed, as these public-house clubs are more expensive—at least 6*d*. a week—they recruit a number of small tradesmen and better-paid artisans, a class of men who to a very great extent can afford to pay medical fees and should not belong to medical aid associations. It is sincerely to be hoped that now a medical union has been formed at Nottingham a determined effort will be made to put an end to this degrading exploitation of medical men by publicans.

UNITED ACTION AT LINCOLN.

AT a meeting of the medical practitioners in Lincoln, held at the Lincoln General Dispensary on March 30th, the following resolutions were unanimously adopted and signed by *all* the medical men practising in Lincoln. The signatures include those of the four medical officers to the two medical institutes in Lincoln. A guarantee fund has been started, and considerably over £100 is already promised.

Resolution.—We, the undersigned medical practitioners in the city of Lincoln, have agreed that the following rules and scale of fees ought to be adopted in all medical clubs under the Friendly Societies Acts and in all medical aid associations:—

1. That no one shall be entitled to medical attendance whose income from all sources shall exceed £2 per week, nor shall anyone be so entitled whose rental shall exceed £20 per annum.
2. Members whose income exceeds £1 per week shall pay for medical attendance on themselves at the rate of 4*s*. 4*d*. per annum, for attendance on their wives 5*s*. per annum, and for attendance on each child 4*s*. 4*d*. per annum, but only four children shall be charged for in any one family.
3. Members whose income does not exceed £1 per week shall pay for medical attendance on themselves at the rate of 4*s*. 4*d*. per annum, for attendance on their wives 4*s*. per annum, and for attendance on their children 4*s*. per annum.
4. Members of juvenile clubs shall pay for medical attendance on themselves at the rate of 4*s*. 4*d*. per annum.
5. That extra fees shall be charged as follows: Dislocations, fractures, and major operations as allowed for by the Local Government Board. Minor operations, 5*s*. Extraction of teeth, 1*s*. Confinements, 10*s*. 6*d*.; operative midwifery, 15*s*. Vaccination, 1*s*. 6*d*.; with calf lymph, 2*s*. 6*d*. Consultations with another practitioner, 5*s*. Examination previous to admission: adults, 2*s*. 6*d*; juveniles, 1*s*. Certificate required by members for other clubs, 1*s*. each certificate.
6. That the medical officers shall receive the whole of the above fees after the deduction of the legitimate expenses.
7. That three months' notice on either side shall be required to terminate the engagement of any medical officer.
8. It is strongly recommended that the medical officers of these societies should be *ex-officio* members of the committee of management.

We further agree and declare that we will not accept office or continue in office as medical officer to any friendly society or medical aid association which does not adopt these principles. We also agree and declare that we will not meet in consultation or otherwise any medical practitioner who accepts office to any of these institutions which have not adopted these principles. In the event of the dismissal of any medical officer on account of his acting in agreement with these decisions we undertake to use our best endeavours to get such officer reinstated, or failing that to do all in our power to secure for him another appointment.

THE ASHANTI EXPEDITION.

(FROM OUR SPECIAL WAR CORRESPONDENT.)

I.

Home Preparations for the Expedition with an account of the Hospital Ship "Coromandel."

WE now commence the six articles dealing exhaustively with the late Ashanti Expedition, which we promised to place before our readers at an early date. In connexion with the description of the *Coromandel* we refer our readers to a paper by Dr. Murray Braidwood, which appears on p. 914.

With the occupation of Kumasi, the arrest of King Prempeh and his entire suite, the surrender of Ashantiland, and the return to England of our forces, another British military undertaking has, without bloodshed happily, been brought to a most successful termination. It perhaps will be as well if a retrospect of the past be taken in order to ascertain how important a factor our English military medical service and its organisation have proved in securing their own measures of success during this short but brilliantly conducted West African campaign. Be it remembered it was surmised from the first that this undertaking would turn out to be a "Doctors' War." Undoubtedly, it has throughout proved to be so. With only two or three exceptions the physician's rather than the surgeon's skill has been largely requisitioned to combat the disastrous effects of this West African malaria, a terrible kind of remittent fever which has not only cost the nation the lives of some distinguished, well-beloved, commissioned officers, and of some 12 non-commissioned officers and men, but has in addition prostrated in sickness a large number of those who, in the pride of life and best of health, went out from England only some three months back to take part in this campaign. In the columns of THE LANCET[1] published a few days before the bulk of the expedition was fairly *en route* certain facts were noticed regarding the peculiar features of the climate likely to be experienced by our countrymen when they reached West Africa, and a few suggestions were at the same time put forward by way of precaution, by the adoption of which it was hoped that some of the climatic evils certain to be encountered might be lessened in their effects if it were not possible to escape them altogether. First of all it was pointed out that malarial remittent fever of a serious type, dysentery, and heat apoplexy were the diseases most likely to be met with by our European troops to be employed on this service. Secondly, it was remarked that the heat, although somewhat great at times during the middle of the day, was not nearly so much to be dreaded as a rapid fall in the temperature at night time, as well as the presence of fogs in these malarious districts which, coming on just after sunset and remaining till perhaps ten or eleven o'clock the following day, would envelop everything in a dense, white, damp mantle. Thirdly, it was urged that the greatest care would have to be exercised in the selection of water intended for drinking or culinary purposes, all reports having proved that water in Africa should be considered and treated as suspicious, polluted as it is, more or less, with animal and vegetable matter, rendering it a potent source of disease, especially as one of the principal causes in producing dysentery, a complaint occupying a premier position amongst the many dangerous ailments in that unhealthy climate. Not only previously to starting but also during the passage out to Cape Coast Castle the medical staff were busily engaged in putting their practical precautions into shape, and by incorporating them in the general list of orders issued to all officers in charge of bodies of troops they left no stone unturned in the way of early warning. The medical orders were as succinct as they were unmistakable, hence no error in their interpretation or meaning could be made by those commanding nor could any excuse have been allowed for disaster arising out of wilful negligence by the careless non-observance of them.

With regard to the general orders, it may first be noted that the men were to have a cup of tea or coffee immediately on rising. Breakfast was to be partaken of in the middle of a march, or about two hours after rising. Secondly, helmets

[1] THE LANCET, Nov. 23rd, 1895.

Digitized by Google

were to be worn from sunrise to sunset. If any coats were taken off during the march they were to be put on again during the halts. Chills were very likely to occur and ought to be guarded against; also wet, perspiration-soaked shirts were to be taken off at midday and hung up to dry, the body at the same time being rubbed with a coarse towel. Cholera belts were also to be worn. Thirdly, men were to restrict themselves to the food as supplied per ration scale, no individual purchases being permitted. They were, moreover, warned against drinking locally-made aerated waters. Fourthly, quinine was issued daily to each man on parade, just after their early cup of coffee. Fifthly, fever and dysentery being the principal diseases to be feared great care was to be used in the selecting, boiling, and filtering of water prior to use. Sixthly, under the heading of Sanitation great stress was laid on camp cleanliness, and any water-supply was to be carefully guarded against pollution by natives bathing or washing therein. Seventhly, bathing was also recommended under certain restrictions.

With reference to the preparations at home it was felt by all who knew the West Coast of Africa well and were concerned in the organisation of the expedition that it would be a risky affair as far as health was concerned even under the most favourable conditions of atmosphere and weather, as well as imprudent and useless, to send out too young or tropically unseasoned men on this expedition. Hence, although offers from individual volunteers for this service were numerous enough—far more, in fact, than the executive could entertain—the authorities wisely contented themselves with selecting only those officers and men whose physique and stamina after careful medical inspection could be relied on. The Composite Service Battalion, a body of picked men from various regiments, was the result of careful choice and wise determination. If any one thing more than another could have demonstrated the wisdom of this new departure in military formation by the Commander-in-Chief it certainly would be found in the way in which the well-chosen units of this composite formation have marched, worked, and borne the climate of Western Africa, for not only have they established a reputation for physical endurance, but they have, in addition, by comparison fairly beaten the coloured West African troops out of the field. Following closely on the heels of the Composite Service Battalion, as far as European troops are concerned, come the West Yorkshire men. They, too, have done very well, but their residence abroad appears in no way to have helped them to withstand the ravages of this climate; on the contrary, it seems to have rendered them more susceptible to its poisonous influence. But be they "Composites," West Yorkshire, West Indian, or Haussas, they one and all have worked manfully and brought to a successful issue a dangerous and very risky campaign the results of which, when compared with those of other nations' attempts in similarly dangerous climates, we ought to be very proud.

Prior to their embarkation the men's kits evidently seem to have been carefully supervised and extremely well attended to. Amongst the various articles introduced flannels and woollen underclothing were much in evidence, and greatly needed they were, too, in such a damp atmosphere as was afterwards experienced. A certain amount of indecision, however, seems to have existed in the minds of the head-quarter staff regarding the outer clothing to be worn by the troops, for several officers and not a few of the privates started on the voyage wearing light karki suits with white helmets. Before arrival at Cape Coast Castle the authorities, for obvious and very prudent reasons, decided on a change of costume, and the Indian dress was discarded in favour of the old and much more comfortable red tunic, while the colour of the helmets was altered from white to light brown. Tommy Atkins, with the ingenuity which usually characterises that individual, soon accommodated himself to the change of tone; one or two applications of a solution obtained from the bottom of his coffee-pot supplied the required colour, and although the tint was not quite so definite in all cases, or so evenly laid on as a true artist could appreciate still it answered its purpose quite well enough, and the aforesaid helmets being subsequently adorned round their bases with red, blue, or yellow bands easily denoted the special branch of the service to which the wearers belonged. But what shall I say concerning those disconsolate young officers who, being warned before leaving that their kit must be reduced to a minimum consistent with propriety, had considerately left their "Sunday-go" reds at home and were not in a position to fall in with the new instructions that were issued? Well, they had, of course, to don their patrols, and keep them on as long as they were under observation; but there were occasions when these thick blue coats proved too oppressive, and then these superfluous belongings were thrown aside *en route*, permitting our fellows to march much better and work considerably harder under their shirt sleeves. I am afraid some of the easy, go-as-you-please style of dress that was frequently observed out there would have shocked the nerves of some old martinets; but, happily for the comfort and health of our men, their day has gone by never to return let me hope; for if the officers who commanded this last expedition so judiciously had worked upon the lines of former days and screwed the men up to full regulation pitch there is no saying what might have happened; but of one thing I feel certain: that if the staff had been less considerate than they have been we should have been brought face to face with a much longer death- and sick-roll than has had to be recorded. All persons do not stand the effects of heat alike. An amount of clothes which one individual can wear in the tropics without any distress whatever will be intolerable to another equally healthy person. This fact was doubtless recognised by those who controlled affairs.

Another feature in the preparations at home has been the fitting out of the hospital ship *Coromandel* for service on the West Coast of Africa, a very important move in the right direction for supplying extra comforts and good medical attendance, with the best of nursing, to the sick and injured at the seat of war. This vessel, which came into the Royal Albert Docks on Feb. 26th from Cape Coast Castle, has been employed by the Government and expensively fitted up for the services required of her. She belongs to, and was chartered from, the Peninsular and Oriental Steam Navigation Company, having been used by them as a passenger steamer for some years past. She was built by Messrs. Caird and Co. of Greenock and is a ship of 4651·58 gross and 2783·6 nett tons register, her length being 400·3 ft., with a beam of 45·3 ft. and a depth of 29·25 ft. The engines are on the triple expansion principle—4200 indicated horse power—and can propel the vessel under favourable circumstances at a fraction over 14 knots per hour. Such a rate of speed, however, cannot always be maintained, for on her passage home, through some foulness of her bottom, caused by lying so long at anchor, a speed of only 12 knots could be got out of her. She is certainly a very handsome-looking craft viewed from without, and possesses a lower, main, and upper or hurricane deck, on the top of which superstructures containing officers' cabins have been erected. For a tropical hospital ship she has wisely been painted white, with a thin red moulding round her to relieve the monotony of colour, whilst her transport indicating number (75) in large block type-figures is on her quarter. This vessel is commanded by a R.N.V. officer, who, possessing the requisite number of hands on board belonging to that naval auxiliary service, is permitted to fly the blue ensign. On going below to the main deck, where the sick officers and men's quarters are, one is particularly struck with the advance that has been made in comfort on the old style. The ancient square canvas cots, swung by clews from bolts in the deck above, have now given place to the more cosy, evenly poised bedsteads capable of a momentum adjustment by a small metal check. These bedsteads can be fixed or they are allowed to swing at pleasure, while the addition of a neat wooden tray at the head of each cot, upon which food, medicine, or books can be placed within easy reach of the invalid is to be commended. Then, too, there are those small toggled lines suspended from the deck above just over the head of each bed, which, on being lowered, can at any moment be grasped by a patient and become a means of raising himself at such times as the nurses or attendants are busily engaged elsewhere. On this deck are the hospitals—the officers' aft and the men's forward. During the passage home the whole of the men's hospital not being required for use, a portion of it—in fact, a space stretching from side to side—has been given up for, and used as, an invalids' smoking-room. A very great boon it has proved too. When the weather became cold, and the men just recovering from fever could no longer pace the deck with any degree of comfort, they could at any rate (thanks to the principal medical officer's consideration for his charge) enjoy their "weed" below. On this deck, too, are the first-class saloon, passengers' cabins, pantries, galleys, engine-room, store-rooms, dispensary, operating-

Digitized by Google

room, waterclosets, and baths. Light and air are admitted by open deck spaces, skylights, and air-shafts, as well as by a series of scuttles arranged at equidistant spaces in two parallel rows round the ship. The upper row, unlike those on the lower deck, consists of circular plateglass discs, inserted into square iron ports which in any ordinary kind of weather can be raised by means of a chain lanyard, and large, square, glass windows inside, corresponding to the size of the port raised, are discovered. Wind and weather permitting these windows can be run back, allowing plenty of air to enter and circulate along the whole length of the ship. Moreover, should the entrance of sunlight prove at all annoying to the invalids and require to be excluded this can be at once effected by letting down a roller-blind put up for that purpose. I was also pleased to notice that the luxury of a punkah had not been overlooked by those who were responsible for the fitting out of the ship.

A word or two with reference to the waterclosets and bathrooms on board the *Coromandel*. The porcelain pans of the closets appear to be quite new and very good. The mechanism seems to work well enough, and being on the pull-down flush principle, they are evidently of the most recent and approved type. But their location appears to be somewhat too near the sick and sleeping accommodation, and the policy of the juxtaposition of bath-rooms, urinals, and waterclosets, only eighteen inches separating these departments from one another, certainly seems to be open to objection. Bath-rooms possibly without much risk might be as near as possible to the dormitories, but surely urinals and waterclosets could, I think, with advantage be placed at a greater distance from the sick than they are on board the *Coromandel*. What is there to prevent these closets being placed somewhere entirely isolated and by themselves?

The dispensary, situated on the port side, is a model of pharmaceutical neatness and arrangement, the area of cabin space devoted to this department being ample and the supply of drugs quite sufficient to satisfy the requirements of the most punctilious of dispensers. Opening out of, and just aft of, the dispensary is the operating-room, fitted up with all the most modern surgical appliances, including an excellent operating table (which, by-the-by, has never yet been used). The space devoted to operative purposes is too narrow and restricted and in any new hospital ship might with advantage be increased, so as not only to allow more elbow-room to the surgeon, but likewise more comfort and advantage to others who might be assisting him.

The *Coromandel* is, very properly, electrically lighted throughout. There is also a large and very complete ice-making plant and distilling apparatus on board, the latter capable of turning out some 3000 gallons of water per diem. I was informed that all water was passed through a filter before being given to any patient. Another great and important addition to creature comforts is to be found in the introduction of a complete laundry plant in this hospital ship. Such a useful desideratum for the purification of soiled linen and the cleansing of dirty clothes has been sadly overlooked by those fitting out steamers for long sea voyages. On this same deck there are winches evidently driven by steam as well as derricks. Now, if there is one thing more than another that causes extreme annoyance to passengers even in the best of health it is the noise caused by these steam-driven lifts when hoisting in or discharging cargo. To the sick the din is simply intolerable. In many of the larger and newer vessels the use of steam has been discontinued in favour of hydraulic power, which is found to be as powerful as, if not more powerful than, steam and is productive of little or no noise whatever, and it might therefore be employed on board vessels intended for hospital use. On the lower deck of the *Coromandel* there is another large hospital; there were some thirteen cases in bed, two rather serious ones, at the time of my visit. The patients one and all expressed themselves very grateful for the comforts and treatment they had received while on board. Want of space forbids my entering more fully into a description of all that was to be seen on or below deck; but I may say the main deck occupied by so many departments leaves but a limited space for promenade purposes—I mean as far as the non-commissioned officers and privates are concerned. True, there is a fine space on the upper or hurricane deck; but in trooping or passenger ships this is exclusively set aside for the use of the officers or first-class passengers; and although the officers belonging to the ship have done their utmost to make everybody comfortable, both on the outward and homeward voyage—and the vessel appears to have fairly well satisfied authorities in her dual capacity of transport and hospital ship—still after all the *Coromandel* is but a makeshift at the best, and I venture to think (many more agreeing with me in this respect) that the time has arrived for the Government to have a properly built and suitably equipped ship for hospital purposes only, a vessel that would be ready at any moment for the particular service required of her. The *Coromandel* was built in 1885 and has been chartered at something like £1000 per week, with an additional cost of nearly £4000 for putting up and taking down her presant fittings. It would be interesting to know how far the accumulated cost of hiring the *Coromandel* would go towards building a suitable vessel.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Ladies' Charity and Lying-in Hospital.

THE troubles at this hospital, referred to in a former letter, have now reached a climax by the resignation of the staff—active, consulting, and out-door—with the exception of three, two of whom are ill and one away from home, nineteen in all. This action has been forced on them by the determination of the committee to push the alteration of the rules guiding the staff in their visits to the hospital, a proceeding so unreasonable that retention of office under such conditions would have rendered them unworthy of the respect of their brethren. It looks uncommonly as if the committee wish the hospital to be looked on as a midwives' charity, so great is their admiration for the female element, which is all-powerful just now. The committee may earn some *kudos* and avoid future injudicious action of a similar character by emancipating themselves from this feminine thraldom. If instead of being guided, as they now appear to be, by a ladies' committee, matron, &c., to the exclusion, practically, of the medical board, they will seek advice on medical matters from those who alone are competent to give it—viz., the medical staff—it will then be all the better for patients, committee, and subscribers. It is to be sincerely hoped that no medical men retaining their self respect will apply for the posts vacated under these circumstances by a competent and self-respecting staff.

Poisoning by "Transfer Pictures."

As the result of an adjourned inquest, held at Seaforth, on the body of a boy named Henry Bridge, evidence was given that some "novelty transfer pictures," which he had been in the habit of attaching to his hands and licking off with his tongue, contained lead paint,[1] and that the post-mortem symptoms were consistent with lead poisoning. The jury returned a verdict that deceased died from the effects of lead poisoning and recommended that the sale of the pictures should be prohibited.

Alleged Insanitary Shop Premises.

At the recent meeting of the Health Committee reference was made to a statement which lately appeared in *Truth* to the effect that the bedrooms occupied by employées in a large drapery establishment were in a dirty and insanitary condition. The medical officer of health, in reply, said that he had received no complaints, anonymous or otherwise, as to the condition of these sleeping apartments, and expressed his surprise that the matter should have been communicated to a London weekly paper to the exclusion of the local press. He also pointed out that all such establishments were under the examination of the corporation inspectors and that cards were provided showing where complaints should be addressed to.

Post-Graduate Course.

Arrangements are in progress for a post-graduate course of fifteen lectures and the same number of demonstrations in medical, surgical, and special subjects. The course will commence on May 12th and terminate on June 30th. Each lecture, which will occupy an hour, will be followed by a demonstration in one of the hospitals lasting from an hour to an hour and a half.

March 31st.

[1] We have tested in our laboratory specimens of these pictures for the ordinary mineral poisons, and one sheet contained a very large quantity of lead.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Vaccination Question at Cheltenham.

AT Cheltenham, on March 26th, a deputation from the Public Health Committee of the corporation waited on the board of guardians and urged that increased facilities should be given for vaccination. Last year the number of people vaccinated was fifteen and last week five. The Health Committee suggested that twenty-four medical men should be selected to vaccinate and revaccinate people at their own homes or at the vaccination offices. It is estimated that there are no less than 1534 unvaccinated children in Cheltenham and that during the past ten or twenty years only 25 per cent. of the people have been vaccinated. It was resolved to ask the sanction of the Local Government Board to the additional facilities for vaccination.

The Bristol Board of Guardians and Vaccination.

At the last meeting of the Bristol board of guardians, held on March 27th, the chairman moved—"That the resolution passed that the vaccination officers do not take proceedings for default in compliance with the Vaccination Acts, pending the issue of the report of the Royal Commission on Vaccination, be rescinded, and that authority be given to the officers to take proceedings from time to time as may be necessary against all persons who neglect to comply with the Vaccination Acts as to the enforcement of vaccination, and who have not been before proceeded against for such neglect." The vice-chairman seconded. The motion, it was explained, was the response to the letter received from the medical officer of health (Dr. D. S. Davies). It was stoutly contested by the anti-vaccinationists. The discussion lasted for an hour and a half, both sides freely quoting statistics. The resolution was, fortunately, adopted—but only by a majority of *one*.

A Gloucester Clergyman's Opinion on Vaccination.

The Rev. Henry Proctor, Vicar of St. Luke's, Gloucester, in the course of a letter to the local press on March 23rd, stated: "There are two families living just outside my garden, in one there are six children, five vaccinated and one not; the unvaccinated child is the only one that has taken small-pox. In the other, out of eight children, one unvaccinated one has died of the disease. In another case there were seven children. The father, mother, and four unvaccinated children have already died, another is hanging between life and death, the other two—who were the only vaccinated members of the family—have not even taken the disease. I could multiply instances, but I will simply add this remark: I am now visiting over 100 small-pox patients from day to day—60 in the hospital and over 40 in their own houses in this parish—and I believe I could undertake to go round from bed to bed and state almost without error which had been vaccinated and which not without any previous knowledge as to the facts, so marked is the difference in the effect of the disease in the two cases." The Vicar of St. Luke's is to be congratulated upon having so well shown in this letter the advantages of vaccination.

The Jenner Memorial Fund.

The Dean and Faculty of the Medical School of University College, Bristol, having consented to receive and permanently locate the valuable collection of mementos of Edward Jenner, known as the "Jenner Relics," it is desired to raise by public subscription the sum of £1500 in order to defray the cost of purchase from Mr. Frederick Mockler of Wotton-under-Edge. Each subscriber of one guinea and upwards will receive when the list is complete a silver medal, and to subscribers of not less than half a guinea a bronze medal will be presented, commemorative of the Jenner Centenary, May 14th, 1896. The Bristol newspapers of March 28th publish a list of subscribers up to March 27th, but the subscriptions at present fall very far short of the sum required. Subscriptions are being received by Messrs. Prescott, Dimsdale, Cave, Tugwell, and Co., bankers, Bristol. Intending subscribers will greatly oblige by sending in their names at their earliest convenience to Mr. W. H. Greville Edwards.

Gallantry of a Medical Man.

The committee of the Royal Humane Society on March 18th awarded their silver medal to Mr. T. H. Morris, M.B., C.M. Glasg., of Tylorstown, Glamorganshire, for distinguished gallantry displayed at the explosion in the Tylorstown Colliery on Jan. 27th, when fifty-seven lives were lost and the mine was wrecked. Dr. Morris entered the pit with an exploring party which, with great difficulty and at the imminent peril of their lives, rendered assistance to the imprisoned miners. The risk to all concerned was extremely great as independently of the danger of being buried alive by the falling coal there was the additional prospect of a second explosion.

Prosecutions by the British Dental Association.

At the instance of the British Dental Association H. W. Shallard and Osborne White, both of Cardiff, were summoned before the local stipendiary magistrate on March 25th for practising as dentists, not being registered under the Act of 1878. They were each fined 40*s.* and costs.

An Infectious Hospital for Dorchester.

On March 25th the new isolation hospital, which has been recently built by the Dorchester municipal authority at a cost of £1200, was opened and several cases of scarlet fever were admitted.

March 30th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Death of the Medical Officer of Health for Sunderland.

MR. J. WOOD, the medical officer of health for Sunderland, died suddenly at Millfield on Wednesday last from syncope. He was only forty years of age and leaves a widow and two boys.

Nurses' Home and Training School, Newcastle-upon-Tyne.

The annual meeting of this valuable institution was held at the home last week, Professor Philipson presiding. From the report it appears there are now seventy nurses and ten probationers. Upon the year's working there has been a profit of £305, and this sum has been divided among the nurses, the amount given to each being regulated by the time she has been on the staff. The great success which has attended the career of the home is very much due to the admirable management of the matron, Miss Emery. 618 cases were nursed last year.

Lecture on the Roentgen Process by Professor Stroud.

A most interesting lecture by Professor Stroud was by request repeated in the large chemical theatre of the Durham College of Science on Monday last to a large audience, when a series of experiments were performed illustrating the effect produced by these mysterious rays.

Stoppage of the Rainton Collieries.

The Marquis of Londonderry called together the men employed in these extensive collieries, some 4000 in number, a few days ago, and explained to them that as he had lost some £15,000 by working the Rainton pits during the year 1895 it would be necessary for him to close them. The noble Marquis, between whom and the miners the very best relations exist, submitted his balance sheet and took the men into his entire confidence. The stoppage of these pits will be a terrible misfortune to the district and to the county of Durham. At present the men work from bank to bank seven hours a day. If they worked longer, as they used to do, when there was more coal in the pits, and it was easier to win than is now the case, it is possible the work might be carried on, but against longer hours is the veto of the union.

Projected Exhibition in Newcastle during the year 1897.

It is proposed to hold during the year 1897, in the city of Newcastle-upon-Tyne, an exhibition on a large scale of local industries, representative of the products of local engineers, shipbuilders, and manufacturers, the proceeds of which are to be devoted to the building fund of the new infirmary. A guarantee of £10,000 is being raised. The infirmary committee has secured the services of Mr. Engel, who has brought several similar ventures to a successful issue in the north of England. It is believed that a substantial sum will by this means be raised.

March 30th.

SUPERANNUATION ALLOWANCE.—Mr. T. Francis, L.R.C.P. Edin., M.R.C.S., has been granted a superannuation allowance by the Brentford board of guardians of £107 13*s.* 4*d.* per annum.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Glasgow.

THE University Court have appointed Dr. H. C. Cameron, Dr. D. C. McVail, and Sheriff Berry as delegates to represent the University at the Congress of the British Institute of Public Health to be held in the University buildings in July next.—The Professional Examinations for degrees in Medicine and Surgery, which have been in progress during the past week, give abundant evidence of the activity of the female undergraduate, for in all the published lists of successful candidates the names of women students are to be found prominent. Similar results are to be traced in the prize lists issued in the Faculty of Arts, where again the names of women students are to be found occupying honourable positions among the prize winners.—Mr. Thos. Gray, B.Sc., F.C.S., Lecturer on Chemistry in Queen Margaret College, has been nominated as secretary of the Scottish Branch of the Society of Chemical Industry, in succession to Mr. Stanley Muir, B.Sc., resigned.

Female Medical Officers.

At a meeting of the Govan parish council on the 26th ult. Mrs. Greenlees moved that lady doctors should be eligible as medical officers under the council. The chairman of the Medical Committee expressed his willingness to assent to the motion, and it was adopted. A medical member of the board, however, ventured to doubt whether the people in all the districts would have confidence in women as medical officers and suggested that the council should rather appoint a number of qualified midwives.

Glasgow Collegiate School Club.

The club, which consists of the "old boys" of the Collegiate School, celebrated its annual dinner on the 26th ult. A number of well-known medical men took part in the proceedings, and the dinner tables were decorated with flowers sent by Dr. Aikman of Guernsey. The newly elected president is Dr. William J. Fleming.

Glasgow Samaritan Hospital.

The annual meeting of the subscribers was held on the 26th ult., Sir James King, Bart., in the chair. The most interesting feature in the report was the announcement that the new hospital buildings will be opened in May next. There is every probability, too, that by that time the entire outlay will have been met by special subscription and that, therefore, the new building will start its career free from debt. The Bellahouston trustees have made a grant of £2000 to the building fund, Lord Overtoun has added £500, and another £500 has been obtained from various sources. There now only remains a balance of £1000, and a special effort is to be made to remove this before the hospital is opened.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Resignation of one of the Members of Parliament for Dublin.

THE sudden and unexpected resignation of the member of parliament for the College Green division of the city of Dublin, Mr. Joseph E. Kenny, M.P., L.R.C.P. Edin., L.R.C.S., L.A.H. Dub., has caused considerable interest in medical circles as well as among the general public. Mr. Kenny is now the coroner for the city of Dublin and is about to resign his seat in the House of Commons on account of the difficulty he finds in attending with sufficient constancy to his duties there. It will be remembered that Dublin has been represented in Parliament for long periods by members of the medical profession such as the late Sir Dominick Corrigan and Dr. Robert Lyons.

The Royal College of Surgeons of Ireland.

More than eighty students entered for the half-yearly preliminary examination at the Royal College of Surgeons in Ireland on March 24th. The fact indicates that the popularity of medicine as a profession here has not diminished.

The Downpatrick Guardians.

With reference to the inquest held in Downpatrick on March 13th,[1] in which the jury blamed the guardians for not providing proper medical assistance when their medical officer was attending the assizes, and to which attention was drawn in the House of Commons, the Local Government Board have instructed their inspector, Dr. Clibborn, to hold a sworn inquiry into the circumstances of the man's death.

Vaccination Prosecutions in Londonderry.

A merchant has been prosecuted by the Londonderry board of guardians for the fourth time under the Compulsory Vaccination Act, he having been fined on the three previous occasions. As the defendant had not complied with the provisions of the Act the guardians on March 14th passed a resolution ordering a fourth prosecution, which took place on March 30th. After it had been proved that the defendant's child, born on Sept. 1st, 1893, had not been vaccinated the father stated that if he were prosecuted twenty-four times he would not allow his child to be vaccinated. As the magistrates were equally divided as to whether or not a penalty should be imposed "no rule" was marked. In another case the same course was taken.

The Battle of the Clubs at Cork.

The fight with the clubs goes on gaily as far as the medical men are concerned. Nearly eighteen months have elapsed and the sixty medical men practising in Cork stand loyally together, shoulder to shoulder, as much so to-day as at the very inception of the movement. Such admirable discipline has necessarily produced a profound impression on the clubs and a public opinion favourable to the medical men is being formed slowly but steadily in Cork. A writer signing himself "Non-Medicus" has done yeoman's service. His letters are models of diction and close reasoning. In scathing terms he criticises the pharisaical hypocrisy exhibited by the clubs in referring to what they are pleased to call "the boycotting of the sick bed" by the medical men, and he aptly reminds them that there was no condemnation of the boycotting of the sick bed when a poor patient suffering from consumption was refused sick pay by his brother members because he had thought fit to ignore the services of the club medical man and call in those of one of the regular practitioners. Rejoinders of that kind have proved too much for club correspondents and "Non-Medicus" remains master of the field.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Health of Marseilles.

AT the last meeting of the Société de Médecine Publique et d'Hygiène Professionnelle M. Genis gave an *aperçu* of the important sanitary works now nearly completed in Marseilles. When the new drainage scheme is applied the sewage of the town will flow into the sea, the cost of the undertaking being 30,000,000 francs. M. Genis complains that the municipality has hitherto taken no steps whatever to utilise the new system of drainage. The Minister of the Interior has vainly urged the city authorities on four occasions to bestir themselves. As things stand, the sewage for the most part flows into the subsoil, which is thus converted into a gigantic cesspool, whilst the 122 kilometres of drains receive only the rainfall. It is not difficult to reconcile with this astonishing supineness the discreditable death-rate of the town—32 per 1000. Only last year the mortality from small-pox was very high. What can be thought of the sanitary notions of a municipality which finds that its duty was performed during the last epidemic of cholera by burning 60,000 francs' worth of sulphur in the drains?

Application of the New Photographic Method.

Professor Pinard exhibited at the Académie de Médecine on the 24th inst. a photograph obtained by the Roentgen process of the fœtus enclosed in a thick-walled uterus which had been preserved in spirit for four months. The image of the skeleton of the full-termed fœtus was clearly seen after an exposure of forty-five minutes. It would appear,

[1] THE LANCET, March 21st, 1896.

Digitized by Google

however, that the living uterine tissues are more easily permeated by the "x" rays, for the images of six fœtuses photographed through the uterus of a living guinea-pig, and shown by Professor Pinard, are more clearly defined.

The Study of Anatomy at Montpellier in Old Times.

M. Gilis, Professor of Anatomy at Montpellier, has recently published his inaugural lecture at that Faculty in the *Revue Scientifique*. He reminded his audience that Montpellier was during the Renaissance the great medical school of France, and that crowds of foreigners repaired thither for educational purposes. Some of these students became celebrated. It is sufficient to quote the names of Felix and Thomas Plater, Felix and Gaspard Bauhin of Bâle, and the Dane, Olaüs Wormius. Despite the difficulty of procuring subjects for dissection anatomy was ardently studied at the Faculty. The method adopted for collecting subjects would hardly commend itself to nineteenth century ideas. At nightfall the students, attired in their cloaks and armed with their swords, would sally forth on resurrectionist expeditions, the scene of their lugubrious operations being the cemetery of the Convent of Saint Denis. Arrived at their destination they would frequently be accorded a rough reception by the monks armed with crossbows. The enthusiasm of the professors for their art sometimes carried them to great lengths. Thus Rondelet begged his friend and colleague, Fontanus, then very ill, to allow his body to be dissected after death. Before his pupils he also dissected the single placenta of twins—his own children. Nor did he shrink from practising a public post-mortem examination of the body of his own son.

Pharmaceutical Frauds.

The Paris Municipal Laboratory has been busy lately in analysing specimens of quinine and antipyrin bought at different drug establishments in the city. Numerous samples were found to be adulterated with bicarbonate of sodium to the extent of 50 per cent. It would appear also that iodoform gauze is extensively coloured with aurantine, and that such adulteration reduces the proportion of iodoform from the normal 25 per cent. to something below $\frac{1}{4}$th per cent. A good plan by which to discover the fraud is to soak the suspected gauze in tepid water, when the aurantine, if present, is dissolved and colours the water a brilliant yellow.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Anti-Malarial Measures.

THE Marchese di Rudini, head of the new Government, has begun well. I am not referring to his success in Chamber and Senate in vindicating his programme, especially as regards the African situation, but rather to the initiative he has taken in furthering a far more commendable policy—the reclamation of derelict or marsh lands from the fevers that haunt them and their subjection to agricultural industry. One of his very first acts has been to issue a series of precautionary measures against the diffusion of epidemics of malaria, taking as his starting-point those localities devoted to rice cultivation. From the Home Office (of which he holds the portfolio) he has, under the advice of the Consiglio Superiore di Sanità, published a paper consisting of six articles or heads, conveying as many ordinances for protecting the labourers in rice cultivation and the districts in which it is carried on. The first deals with the appointment of a Special Commission composed of the provincial medical authorities, an engineer, and an agricultural expert, charged with the duty of testing and reporting to the Prefect the cases in which demands for rice cultivation may be safely conceded—cases, that is to say, where the concession of such demand can be freely granted without compromising the health of the labourer or the sanitary conditions of the vicinity. There are rules in existence for the protection of both these interests—that of the working hands and that of the health of the surrounding population—and guided by these the Commission will proceed to grant or withhold the concessions alluded to. Should the concessionnaire in the process of carrying out his operations depart from the prescriptions laid down the Prefect shall then be empowered to withdraw the privilege conceded. Nay, more; if, in spite of all due observance of those prescriptions, the locality or the soil under rice cultivation develop unforeseen conditions prejudicial to health, the Prefect shall again be entitled to intervene and withdraw the concession or suppress the industry for a given number of years, always subject of course in so doing to the provincial sanitary council as advised by the Commission above indicated. The concessionnaire shall have no claim to indemnity for loss by the withdrawal of his concession. Other prescriptions relative to what may be called the business aspect rather than the hygienic aspect of these ordinances are minutely given and need not be detailed here; but the step taken by the Di Rudini administration is in all respects a meritorious one and forms, let us hope, the prelude to others equally calculated to raise the standard of health in the all too severely visited agricultural and pastoral regions of Italy. As I write the most gratifying report is handed to me on the Colonia Agricola di Ostia—a district on the Latin shore so haunted by the palustral miasm that ten years ago it was habitable only in winter, being for nine months out of the twelve a scene of desolation and death. A company from Ravenna to which the cultivation of this "regione morta" was conceded has been able to overcome by drainage and agriculture the pestiferous influences of the "stagno di Ostia," and at the cost of some 200,000 fr. has established a sanitary and agricultural "plant" which will not only maintain but extend the anti-malarial conquests already achieved. Only eighteen miles from Rome, that region, once an opprobrium to the civilisation and enterprise of the capital of United Italy, is now on the way to become a standing honour to both, and the institution of a local pharmacy and the provision of a medical staff are now only required to put it on a level with the best of those reclamations which year by year are lessening the area of "Italia irredenta."

March 28th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Gratuitous Hospital Treatment.

AS I have already stated,[1] the Vienna Medical Chamber has energetically protested against the abuse of hospitals by well-to-do patients, and has even proposed that those who apply for gratuitous treatment should be required to produce evidence that they are really necessitous. The managers of the Polyclinic, however, are satisfied with things as they are and point out in a pamphlet that the number of well-to-do people gratuitously attended in their establishment hardly exceeds 5 per cent. As the number of out-patients treated there amounts to about 50,000 in the course of a year it follows that the Polyclinic has been resorted to by about 3000 patients who were in a position to pay for medical assistance. The public, in fact, believe that they have a right to gratuitous medical attendance, and one of the consequences is that there are a great many medical men whose income hardly amounts to £40 a year. The number of practitioners in Vienna has, moreover, increased from 844 in 1870 to 1179 in 1880 and to 2000 in 1895; this is in a population of 1,400,000, whereas in Berlin, with its 1,800,000 inhabitants, there are only 1900 medical men. At a meeting of the Medical Society of the Southern Vienna Districts Dr. Kürth said that if this state of matters continues the poor medical man will soon form a counterpart to the poor country schoolmaster.

The Function of Hair.

A highly interesting paper on the Function of Hair has been read by Professor Exner at a meeting of the Medical Society. He said that writers have hitherto occupied themselves mainly with speculations on the circumstances which have led to man becoming denuded of his hairy covering. The hairs, however, are not only degenerated organs, but have also to fulfil some functions. There is a group, such as the eyelashes and eyebrows, for instance, which are sensorial organs, possessing tactile functions, and, moreover, serve as a protection to the eyes. In places where two integumentary surfaces are in contact, such as in the axillary region and in the fold between the scrotum or the labia majora and the leg, they act as rollers and facilitate the gliding of the integumentary surfaces on each other. A third function of the hairs consists in the equalisation of surface temperature.

[1] THE LANCET, Aug. 24th, 1895, p. 473.

Digitized by Google

There is no doubt that the hair of the scalp protects the head against external cold and also prevents the loss of heat through the very low thermal conductivity of the hair cylinders and of the cushion of air intermingled with them.

The School of Medicine.

According to a report which has just been published the Vienna School of Medicine was attended by 3674 students during the past winter half-year, comprising 2211 ordinary and 1463 extraordinary students. The teaching staff consisted of twenty-nine ordinary professors, thirty-four extraordinary professors, and ninety-three *privat-docents* and assistants.

March 30th.

MEDICAL TRIAL.

QUEEN'S BENCH DIVISION, HIGH COURT OF JUSTICE.

(Before Mr. Justice HAWKINS.)

KITSON *v.* PLAYFAIR AND WIFE.

THIS case, part of which we reported in our issue of March 28th, was concluded on Friday last. We continue the report:—

Mr. Arthur Kitson, the plaintiff's husband, examined by Mr. Tindal Atkinson, said he left Sydney at the end of September or beginning of October, 1892. His wife was always suffering and in the doctor's hands. When he left Sydney he went to Port Darwin. His wife was then so ill that Dr. Ogg advised a long sea voyage. He wrote to his brother James of this, and saying that he intended sending her to England. From Port Darwin he went to Hongkong on his way to Honolulu. He had a letter from his wife on June 6th, 1894, which he had destroyed. This letter had reference to the accusations made by Dr. Playfair. He received another letter at Sydney to the same effect. He left for England as soon as he could, and arrived about Aug. 29th, 1894. She communicated to him all that had occurred and placed in his hands all the correspondence which had passed between her and Dr. Playfair. He then wrote to Sir James Kitson.

Cross-examined by Sir Frank Lockwood: He allowed his family to believe that he had surreptitiously visited England. He did so because he thought they wished to believe it. He had received letters from Sir James Kitson and Dr. Playfair withdrawing the accusations "after a fashion."

This closed the case for the plaintiffs and Sir F. Lockwood addressed the jury on behalf of the defendants. His first duty was to submit to his lordship that the occasions on which the libel and slander were published were privileged. Having regard to the relations existing between the parties he contended that the communication by Dr. Playfair to his wife was justifiable and the communication was privileged unless it could be shown that he was actuated by an indirect motive or by malice *per se*. With regard to the communication between Mrs. Playfair and Sir James Kitson, the communication was made by a sister to her brother in regard to the conduct of their sister-in-law, and they had a joint interest in the communication being made. Here, again, unless it could be shown that Mrs. Playfair was actuated by some malice or indirect motive the occasion was privileged.

Mr. Justice Hawkins: The question of actual relationship does not seem to me to cover the ground. Would there be privilege if the communication were made to an aunt?

Sir F. Lockwood: The point here is that these people were deeply interested in the conduct of their brother's wife, with whom they were associating on terms of intimacy.

Sir F. Lockwood, continuing, said he knew the great difficulties which lay in his way in putting forward Dr. Playfair's view of the case. Mr. Walton had drawn a pathetic picture of the sufferings of Mrs. Kitson, which he had been able to supplement to some extent by the testimony he had called. He was not going to ask the jury to approach the case in a hard-hearted way, but to judge temperately and fairly of the conduct of Dr. Playfair. Mr. Walton had charged Dr. Playfair with being a cruel and hard inquisitor, and made it impossible that his speech should go before the world uncontradicted. This man was the first to throw open his door to her. Shortly after she arrived in England Dr. Playfair examined her. She had complained to Mrs. Playfair of the state of her health and that lady suggested that Mrs. Arthur Kitson should consult her husband. Dr. Playfair examined her generally as to her physical condition and stated that there was nothing organically wrong. With reference to what occurred later he would not ask the jury to say that this lady had had a miscarriage or to say that she had not been chaste. All he asked them to say was that Dr. Williams was justified in the conclusion he had come to and that he *bond-fide* believed to be true that which he communicated to Mrs. Playfair.

Dr. William Smoult Playfair, examined by Mr. Charles Matthews, said he was Doctor of Medicine, Fellow of the Royal College of Physicians of London, Professor of Obstetric Medicine and teacher of diseases of women and children at King's College Hospital. His feelings towards the plaintiff were those of complete friendship. After her arrival in England she consulted him with regard to her health, and he made an examination as to the general state of her health. On Jan. 16th, 1894, he was called in by Dr. Williams. Before seeing her he met Dr. Williams and talked over the case, and the latter described it to him. They afterwards saw the lady together. She seemed generally ill, and complained of some hæmorrhage which had existed for some time. He thought the trouble was a somewhat profuse period. On Feb. 23rd he saw Dr. Williams in consultation. In the course of the examination he found the neck of the womb dilated to the size of a five shilling piece. Within the neck of the womb and above it he found a soft fungated mass, which he at first took to be a intra-uterine cancerous growth, but it was impossible to make a sufficiently complete diagnosis. He sent Dr. Williams for some chloroform, and when he returned they put the plaintiff under its influence. He then found that the mass was not growing from the interior of the womb and that it was easily scooped out and removed. He then found the mass to be a portion of fresh placental tissue of a spongy consistence and containing fresh blood in its interstices. After the operation he formed the opinion that Mrs. Kitson had had a recent miscarriage. There were not two administrations of chloroform. It was one continuous administration, with a stoppage while he showed Dr. Williams the substance which had been removed. He did not make use of the words, "I do not know what else it can be. I know very little about her, she may have been playing hanky-panky." Dr. Williams did not say, "I do not think it can be anything like that. She has submitted to every examination and been perfectly candid." She did not struggle up and say: "Oh, Dr. Playfair, for God's sake let me go now if you think there is anything wrong." It would have been impossible. He did not pat her and say: "There, there, my dear, it is all right; we think it is a cancerous growth." He did not say, "Give her some more." The substance he removed was certainly not, in his opinion, a blighted ovum. It was a piece of fresh placental tissue. A blighted ovum was the entire product of conception which had perished in the womb and undergone certain degenerative changes and which was eventually thrown off. It varied in size from that of a duck's egg to that of a small melon. He would not expect it to lie loose in the uterine cavity.

Cross-examined by Mr. Lawson Walton, he said that it was on the assumption that Mr. Arthur Kitson had been in Australia that he formed an opinion adverse to the plaintiff's honour. He formed it solely on his medical examination.

Mr. Lawson Walton: Do you retain that opinion still?

Dr. Playfair appealed to his lordship as to whether he was obliged to answer that question and eventually replied: I do.

Mr. Lawson Walton: Then why had you not the courage and manliness to put that on record in your pleadings?

Witness: I placed the case in the hands of eminent counsel and I was satisfied to act on their advice.

Mr. Lawson Walton: You thought it more politic?

Witness: I thought it more judicious.

Mr. Lawson Walton: Then, sir, why did you not insist on your counsel raising that issue in order that this lady might have the opportunity of refuting it?

Witness: Because I do not think it judicious to insist on raising issues not advised by counsel.

Mr. Lawson Walton: Do you still tell the jury that, notwithstanding the lady's oath and her husband's and the opinion of Dr. Spencer, you persist in your opinion?

Witness: I do. Continuing, witness said in coming to this conclusion he rejected all but medical considerations. He rejected all moral considerations, and the fact that plaintiff called in to attend her a member of her own family. It did not strike him as extraordinary that she asked him to wait until her husband came back. Dr. Spencer's evidence counted for nothing in his mind.

Mr. Lawson Walton: How much evidence of other doctors would serve to change your opinion?

Witness: No amount; for none saw it under the same conditions as myself. He never believed that Mr. Arthur Kitson had been in England.

Re-examined by Sir Frank Lockwood: He did not believe the statement; he accepted it that Mr. Arthur Kitson had been in England. The substance referred to in *Charpentier* bore no relation to the substance he removed from plaintiff. He had no desire to make imputations of unchastity against Mrs. Kitson.

Dr. Muzio Williams was then examined by Mr. Matthews, and detailed his attendance on Mrs. Kitson and the calling in of Dr. Playfair. On Feb. 23rd Dr. Playfair sent him to get some chloroform, and he administered it while Dr. Playfair made the examination and performed the operation. Dr. Playfair removed a piece of fresh placental tissue and its condition indicated to him (Dr. Williams) a three months' pregnancy. The tissue was spongy and contained fresh blood. Dr. Playfair said "This is terrible. It is a piece of placenta. I did not know the lady before she married Arthur Kitson." Witness did not recollect Dr. Playfair having said anything more. Shortly after Dr. Playfair left. Mrs. Kitson was not conscious when he left the room. He did not remember Dr. Playfair using the words, "I know very little about her. She may have been playing hanky-panky." He (witness) did not say "I do not think it can be anything like that," neither did he say she had submitted to every examination and been perfectly candid. The lady did not struggle up and say the words she alleged she uttered. He (witness) patted her and said, "It is all right." She said, "What is it you accuse me of?" I said, "We have not accused you of anything; we have not quite finished, go on breathing." Nothing was said about the cancerous growth. Witness was then cross-examined by Mr. Lawson Walton as to his action in refusing to give any information to plaintiff's solicitors except through defendant's solicitors.

Dr. Hugh Playfair, curator of King's College Museum, was next examined. He said the substance submitted to him by Dr. Playfair was undoubtedly placenta, which had only very recently ceased discharging its functions. Microscopical examination confirmed this opinion. Cross-examined by Mr. Lawson Walton witness said he heard Dr. Spencer refer to a period of eighteen months, but that was quite impossible. At the outside the piece could not have been more than ten months old.

Re-examined by Sir Frank Lockwood: A placenta of eighteen months would be perfectly different in appearance. It would be tough, hard, and fibrous, and partially discoloured. Moreover, the microscopical appearances would be totally different. There would be signs of degeneration and atrophy of the chorionic villi and an enormous overgrowth of fibrous tissue. None of these conditions were in the substance submitted to him.

Mr. Bland Sutton, professor of pathology at King's College, gave evidence as to having received specimens for examination which were undoubtedly placental tissue. It was not possible that this could have been formed in December, 1892, and removed in March, 1894.

Sir John Williams, examined by Sir F. Lockwood, gave evidence substantiating in the main the evidence of the previous medical witnesses. With regard to the matter of professional confidence, witness said there was no hard-and-fast line in the maintenance of professional confidence.

Sir Frank Lockwood: What are the considerations which do affect medical men in regard to professional confidence?

Witness: As a general rule medical men should hold inviolate professional confidence.

Digitized by Google

Sir Frank Lockwood: Are there exceptions to that rule?

Witness: The exceptions are when there are higher claims upon the man, such as in a court of justice. With regard to crime, a medical man is obliged to inform the Public Prosecutor of any crime which has been committed or it is intended to commit. The higher claims that a man's wife and children have upon him justify him in taking every measure to protect them.

Cross-examined by Mr. Lawson Walton: Do you consider secrets obtained in the course of professional attendance the secrets of the patient or the secrets of the medical man and under the absolute control of the medical men?

Witness: It is the secret of the patient.

Mr. Lawson Walton: Do you consider the medical man is bound to consult the patient before he divulges that secret?

Witness: No.

Mr. Lawson Walton: Do you say that the medical man is the sole judge without appeal of the circumstances under which he should publish that knowledge to the world?

Witness: He is and he must be.

Mr. Lawson Walton: If he thinks he is entitled to do so, is he at liberty, if he thinks it is justified, to divulge it to anyone?

Witness: No, I do not think so.

Mr. Lawson Walton: Do you contend that the medical man is entitled, whether he be discreet or indiscreet, to disclose the secret without communicating with his patient?

Witness: I cannot answer that question yes or no.

Mr. Lawson Walton: Who is to decide the circumstances under which he may publish the secret to the world?

Witness: The courts of law in some instances.

Mr. Justice Hawkins: Suppose a medical man were called in to attend a woman, and in the course of his professional attendance he discovers that she has attempted to procure an abortion. That being a crime under the law, would it be his duty to go and tell the Public Prosecutor?

Witness: The answer of the College of Physicians to that very question was "Yes."[1]

Mr. Justice Hawkins: Then all I can say is that it will make me very chary in the selection of my medical man.

Mr. Lawson Walton: Who is to be the judge of the justification of the claim of wife and children to allow of the divulging of a secret the property of a patient?

Witness: The medical man himself.

Mr. Lawson Walton: Who is to say the medical man is wrong?

Witness: A court of law may.

Sir William Broadbent, examined, said he was a Doctor of Medicine and a Fellow of the Royal College of Physicians of London and Senior Censor on the board of the Royal College of Physicians.

Sir Frank Lockwood: Do you agree with the rule with regard to confidence in your profession as expressed by Sir John Williams?

Witness: The rule is a very strong unwritten law that no confidence made to a medical man shall be divulged.

Sir Frank Lockwood: What are the exceptions?

Witness: The exceptions are such as have been stated by Sir John Williams, that we are compelled to divulge confidences in a court of law and sometimes in order to prevent crimes. There are, in my judgment, also certain circumstances under which as a man of honour and acting under a strong sense of duty it might be necessary to divulge what is called a professional secret.

Sir Frank Lockwood: Do you recognise the exceptions made by Sir John Williams in favour of wife and family if it is a case where the medical man has clear convictions?

Witness: I think so. It is difficult to formulate an abstract opinion of this kind. It is conceivable that it might be necessary to divulge secrets under various circumstances.

Cross-examined by Mr. Lawson Walton: The disclosure should only be made in the last resort when it becomes inevitable?

Witness: Certainly.

Mr. Lawson Walton: If the object can be effected in a way short of divulging a secret, it ought to be done in that way?

Witness: Yes.

Dr. Champneys, F.R.C.P., agreed with the medical evidence of Sir John Williams respecting a blighted ovum, and

Sir Wm. Priestley, F.R.C.P., also gave testimony in respect of the same evidence.

This closed the case for the defence, and Sir Frank Lockwood and Mr. Lawson Walton addressed the jury on behalf of their respective clients.

Mr. Justice Hawkins, in summing up, said the plaintiff had brought this action for slander and libel. The charge made against her was that after she had come to England from Australia she had had adulterous intercourse with some person, the result of which was a miscarriage. To that the defendant had pleaded, first of all, that the words were not spoken or published at all; and, secondly, that if they were, they were published under circumstances which did not afford justification, but which robbed the libel or slander of its malicious character.

Mr. Justice Hawkins then dealt with the main facts of the case leading up to the question of privilege. The action was brought for the communication of the libel not only to Mrs. Kitson, but to Sir James Kitson, so that the question as between the husband and wife was not now before them. But since that question was discussed in the course of the case he would touch upon it, though what he said must not be taken to be a ruling on the point. The medical profession might, no doubt, discuss among themselves rules for their own guidance, but they had no power to impose the rules they made upon the public. With regard to the question of the exception to the unwritten rule of professional secrecy, he did not altogether agree with the medical evidence on that point. With regard to cases where it was said the doctor should inform the Public Prosecutor, the judge himself might in some cases refuse to commit a medical man for contempt in refusing to reveal confidences. Each case would be governed by the particular circumstances, and the ruling of the judge, deciding no doubt according to the law, would be the test. If the doctor were called in merely to attend a woman and give her advice his lordship doubted very much whether he would be justified in going to the police and saying, "I have attended a poor woman who has been trying to procure an abortion." That would be a monstrous cruelty. The rule did not meet with his approbation and he hoped it would not meet with the approbation of anybody else. There were cases, no doubt, in which it was obvious that a medical man should inform. He only protested against that rule being said to be applicable to all cases. There was a third objection—namely, a communication between the doctor and his wife or children in order that they might be protected. That required a great deal of consideration and it was a very delicate question.

[His lordship commented upon the action of Dr. Playfair in refusing to allow Mrs. Kitson an interview in order to clear herself, and, reading the correspondence, referred to the tight corner in which Mrs. Kitson had been placed.]

Mr. Justice Hawkins submitted the following questions to the jury: (1) Were the words uttered as alleged true? (2) Did the defendants believe the words to be true? (3) Were they uttered in good faith? (4) Were they uttered not from a mere sense of duty, or from some indirect motive or to gratify feelings of ill-will, anger, or irritation against the plaintiff or her husband?

The jury then left the box, and after an absence of about an hour answered the first question in the affirmative. To the second they said, "Yes; but Dr. Playfair did not afford the plaintiff reasonable time and opportunity for an explanation." To the third question they answered, "No," and to the fourth that the words were not uttered from a mere sense of duty but from an indirect motive. Damages were assessed at £2,000.

Mr. C. W. Mathews: I apply for a stay of execution on the ground that there was no evidence of malice.

Mr. Justice Hawkins: I will certainly not grant it on that ground.

Mr. C. W. Mathews: I ask for it on the ground that the occasion was privileged ——

Mr. Justice Hawkins: But malice is found by the jury.

By Mr. C. W. Mathews: And also on the ground that the damages are excessive.

Mr. Justice Hawkins: No.

Eventually his lordship agreed to consider the matter on Monday morning, March 30th, when

Sir Frank Lockwood renewed the application for stay of execution pending appeal.

Mr. Justice Hawkins: I have fully considered the matter and I have made up my mind. If I had disapproved of the verdict of the jury I should have granted the application for a stay of execution in the first instance upon terms. I always think one ought not to interfere with the verdict of the jury unless one is satisfied it is wrong. I ought to let you go to the Court of Appeal for the stay.

Sir F. Lockwood: My lord, I have come to an arrangement with my learned friend which will relieve us from going to the Court of Appeal. We have arranged for a stay by consent on the terms of a sum of money being paid over to the plaintiff unconditionally.

[1] Our special reporter was under the impression that the answer of the witness was as recorded above, but Sir John Williams has since written to The Times to correct this statement, which should be: "The last legal opinion upon that very question obtained by the Royal College of Physicians is 'Yes.'"

Medical News.

VICTORIA UNIVERSITY: FACULTY OF MEDICINE.—

The following candidates passed the under-mentioned examinations in March:—

SECOND EXAMINATION.

A. Anatomy and Physiology.—J. W. Aldred, Owens College; E. L. Anderson, University College; D. A. Ashton, Owens College; J. W. Barber, Yorkshire College; T. T. Bark, University College; W. J. S. Bythell, Owens College; John Craig, Owens College; Willie Cunliffe, Owens College; Harry Dunk, Yorkshire College; H. M. Fletcher, University College; E. W. Floyd, Owens College; J. P. H. Greenhalgh, Owens College; J. T. Grierson, University College; W. S. Henderson, University College; E. M. Hime, Yorkshire College; J. A. Howard, University College; Frederic Hoyle, Owens College; H. H. McNabb, Owens College; E. J. Martin, Owens College; B. C. Middleton, Owens College; Joseph Moreton, Owens College; Edgar Newhouse, Yorkshire College; W. P. Noall, Owens College; Harry Osborne, Owens College; W. F. Oyston, Yorkshire College; J. A. Reed, Yorkshire College; W. H. Richardson, Owens College; Ambrose Spong, Yorkshire College; Edward Trotter, Yorkshire College; Edward Turton, Yorkshire College; G. C. Walker, University College; T. H. Wignall, Owens College; and O. H. Woodcock, Owens College.

B. Materia Medica and Pharmacy.—H. M. Cockcroft, Owens College; P. A. L. Foulds, Owens College; E. C. Hulme, Owens College; S. C. Moore, University College; Joseph Moreton, Owens College; William Sankey, Owens College; W. H. Tattersall, Owens College; and O. H. Woodcock, Owens College.

The Scholarship in Medicine was awarded to Joseph Moreton, Owens College.

FINAL EXAMINATION.

Part I.—R. W. Bollans, Yorkshire College; Francis Darlow, Yorkshire College; J. H. Davies, University College; J. F. Hodgson, Owens College; E. E. Laslett, University College; Alexander Lawson, Owens College; G. G. Lawson, University College; Henry MacKennal, Owens College; F. E. Marshall, University College; Frank Prichard, Owens College; Graham Renshaw, Owens College; A. L. Rhind, Owens College; A. B. Smallman, Owens College; H. de P. B. Veale, Yorkshire College; Alfred Wightwick, Owens College; D. O. Williams, Yorkshire College; R. H. Wilshaw, Owens College; and William Wright, Owens College.

Part II.—W. S. Badger, University College; G. H. Bishop, Owens College; S. E. Christophers, University College; William Dyson, Owens College; John Hartley, Owens College; John Hay, University College; J. A. MacLaren, Owens College; D. W. Main, University College; J. F. Rimmer, Owens College; E. A. Smith, University College; and Bernard Stahlknecht, University College.

The following were awarded Honours:—*Class I.*: S. E. Christophers,

Digitized by Google

University College, and E. A. Smith, University College. *Class II.*: John Hay, University College.

UNIVERSITY OF GLASGOW.—The following have passed the First Professional Examination (new regulations) for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subject or subjects indicated after their respective names (B., botany; Z., zoology, P., physics; C., chemistry):—

Adolph Anderson, B., P.; John Anderson, Z., P.; Gavin Barbour, Z., P.; James Oastler Barclay, Z., P.; Ernest George Dryden Benson, B., Z.; Alexander Binning, Z., P.; William Herbert Brown, Z., P.; John Douglas Brownlie, Z., P.; Patrick Thomas Cairns, P., C.; Thomas Bullough Calland, Z., P.; Samuel James Cameron, Z., P.; Thomas Carruthers, M.A., B., Z., C.; Edward Provan Cathcart, B., Z., P.; Robert Clark, Z., P.; John Craig, Z., C.; George Morris Crawford, C.; Charles Peter Garvie Crichton, P., C.; Charles Campbell Cuthbert, B., P.; Arch. William Wallace Davidson, B., C.; James Davidson, M.A., B, Z.; Alexander Doig, Z., P.; John Downie, Z., P.; John Pinkerton Duncan, Z.; John Forrest, Z., P.; Eric Dalrymple Gairdner, P., C.; George Gardner, P.; John Gardner, B., C.; George Garry, B., P.; James Gemmell, B., C.; William Girvan, B., Z.; John Gracie, Z., C.; John Gregor, Z., P.; Robert Archibald Hamilton, Z., P.; Archibald Wilson Harrington, B., C.; Leslie Charles Broughton Head, B., C.; James Macpherson Henry, Z., P.; Thomas Inglis, B., P., C.; John Kennedy, B., C.; Alexander King, Z., P.; William Henry Kirk, B., P.; James Dickson Laidlaw, B., P.; John Francis Lambie, Z., P.; Norman Maclean Leys, Z.; James Dunlop Lickley, Z., P.; Donald M'Farlane Livingstone, Z., P.; David Longwill, B., P.; Jacob Mains, Z., P.; Andrew Mair, Z., P.; Robert M'Nab Marshall, Z., P.; Allan Martin, M.A., Z., C.; James Millar, B., C.; Hugh Miller, Z., C.; William Archibald Mills, B., Z.; Alexander Robert Moir, B., Z., P., C.; Peter Moir, B., Z., P., C.; Daniel Morrison, B., P.; Alexander Munro, Z., P.; James Hogg MacDonald, B., C.; James William M'Dougall, B.; George Steventon M'Kinnon, Z., P.; James Mackinnon, B., P.; Charles Forbes Maclean, C.; Norman Forbes Macleod, C.; John M'Millan, C.; Burgess M'Phee, B., Z.; Thomas Neill, Z., C.; Robert Orr, Z., C.; James Patrick, B., Z., P.; William Barr Inglis Pollock, Z., C.; John Reid (Lanark), B., Z.; Peter Mackenzie Reid, Z., P.; John Duncan Richmond, Z., P.; William Alexander Riddell, B., P.; Henry Thomas Roberts, B., Z., P., C.; Arthur Robin, B., C.; James Crawford Ross, Z., P.; David Russell, Z., P.; Malcolm Scott, P., C.; David Shannon, Z., P.; Edgar William Sharp, Z., P.; Malcolm Alexander Sinclair, B., P.; Archibald Smellie, B., C.; John Steele Smith, B.; David Spence, Z., P.; Peter Alexander Steven, B., C.; Andrew Stewart, Z., P.; John Strathearn, Z., P.; Charles Pinkerton Thomson, C.; Joseph Swinburne Townley, B., Z.; James Cameron Turnbull, Z., P.; John Turnbull, P., C.; Arthur Vost, C.; Albert Ernest Wainwright, Z., P.; George White, Z., P.; Robert George White, Z.; George Henry Wildish, B.; Hugh Patrick Wright, Z., P.; and John Young (Bearsden), B., P. *Women*: Lizzie Thomson Fraser, P., C.; Helen Mary Gordon, P.; Jane Grant, B., Z.; Lila Stephenson Greig, P., C.; Catherine Spence Howden, P., C.; Mary Forbes Liston, P., C.; Jean Marion Farie Marshall, P., C.; Mary Lauchline M'Neill, B., C.; Maud Ada Richards, P., C.; Margaret Mitchell Ritchie, P., C.; Mary Ann Thompson Ritchings, Z., P.; Sara Maude Robertson, Z.; and Gert. Florence Fleetwood Taylor, B., Z.

The following have passed the Second Professional Examination (old regulations) for the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.):—

James Andrew, Robert Adair Lockhart, George Murray, Hugh McIntyre, Charles David Picken, and Charles Edward Cortis Stanford, B.Sc. *Woman*: Martha Jane Gilmore Cox.

The following have passed the Second Professional Examination (new regulations) for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subject or subjects indicated after their respective names (A., anatomy; P., physiology; M., materia medica and therapeutics):—

John Aitken, A., P.; George Alexander, A.P.; Arthur James Ballantyne, A., P.; Andrew Aitken Barclay, A., P.; James Barrowman, A., P.; William Bennett, A., P.; James Symond Beveridge, A., P.; George MacLellan Blair, A., P.; John George Wilson Boleyn, M.; Theodore Belchambers Broadway, M.; John Brunton, A., P.; Wm. Cochran Burns, M.; Robert Carswell, M.A., A., P., Alex. Henderson Cassells, A.; Andrew Clark, A., P.; Robert Crawford, M.; John Crow, M.; John Lithgow Davie, A.; Robert Douglas, M.A., A., P.; Alexander Garrow, A., P.; James Garden Green, A.; David Sloan Harvey, A., P.; Harold Smith Heap, A., P.; John Henderson, A., P.; Thomas Hunter, M.A., B.Sc., M.; Ernest Frederick Lionel de Jersey, P., M.; Edward William Reese Jones, A., P.; William Wallace Keir, A., P.; Alexander Millar Lindsay, M.; Robert Lunan, M.; Alexander Matheson, A., P.; James Blakeley Miller, A., P.; James Alex. Mitchell, A., P.; Percival Ambler Mitchell, A., P.; Murdoch Macdonald, M.; Arch. Turner Macewan, A., P., M.; Dugald M'Kinlay, A., P.; Roderick Reid Macnicol, M.A., A., P.; James M'Whir, M.; Robert Niven, A., P.; Percival Leslie Pearce, A., P.; Joseph Wilkie Scott, A., P.; Robert Scott, M.; John Shaw, M.A., A., P.; David Ap Simon, A.; John Macfarlane Sloan, A., P.; Francis Stevenson, P.; Frederick Ernest Stokes, A., P.; James Strang, M.; Thomas Morton Strang, A., P.; James Douglas Carnon Swan, M.; Daniel Rees Thomas, P.; William James Alexander Walker, M.; Ernest Watt, M.; Edward Roberts Weir, M.; Jas. Patterson Wilson, A., P.; and John Wotherspoon, M. *Women*—Daisy Annabelle Bennett, P., M.; Agnes Forbes Blackadder, A., P., M.; Lucy Buckley, B.Sc., M.; Mary Longmire, A., P.; Karen Margrethe Myhre, A., P.; Eva M'Call, A., P., M.; Minna Amelia Macfarlane, M.; Margaret Wallace Howie M'Neil, A., P.; Mabel Catharine Poulter, A., P., M.; Jean Effie Prowse, A.; Agnes Renton Robson, M.; Marion Jamieson Ross, A., P.; Catherine Love Smith, M.; and Sara Whiteford, P.

The following have passed the Third Professional Examination (old regulations) for the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.):—

(*A*) *Including Pathology.*—James Francis Agnew, William Buchan Armstrong, John Tait Bowie, Charles Cairnie, M.A., James Banks Cumming, James Donald Holmes, Archibald Livingston, George Bain Murdoch, Neil M'Callum, John Allan Craigie Macewen, B.Sc., Joseph M'Gowan, Robert Shanks, and James Weir. *Women.*—Annie Kirkby Anderson, Norah Kemp, Roberta Henrietta Margueretta Stewart, and Merbai Ardesir Vakil, B.A.

(*B*) *Not including Pathology.*—Andrew Phillips Aitken, John Ritchie Burns, John Herbert Lawson, Robert Hugh Meikle, James Millar, and John Alexander Paton.

The following have passed the Third Professional Examination (new regulations) for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subject or subjects indicated after their respective names (P., pathology; M., medical jurisprudence and public health):—

Francis James Charteris, P., M.; George Clark, P., M.; George William Coats, P.; James Duncan Cochran, P., M.; Joseph Muir Corbett, P., M.; Walter Scobie Findlay, M.A., P., M.; Adrian Andrew Forrester, P., M.; Lawrence Whitaker Harrison, P., M.; William Mitchell Lindsay, P.; William Glen Liston, P., M.; James M'Haffie, P., M.; David M'Kail, P., M.; Norman Emil Henry Scott, P., M.; Samuel Macfarlane Sloan, P., M.; David Steele Smith, P., M.; and Mathew Logan Taylor, P., M.

UNIVERSITY OF ST. ANDREWS.—The following registered medical practitioners having passed the fequired examinations had the degree of Doctor of Medicine conferred upon them on March 27th, 1896:—

Beatty, Thomas Carlyle, L.R.C.P.Edin., F.R.C.S.Edin., L.S.A. Lond., Clacton-on-Sea.
Blake, Thomas William, M.R.C.S.Eng., Bournemouth.
Edmiston, John Clark, L.F.P.S.Glasg., Glasgow.
Gramshaw, Farbrace Sidney, L.A.H.Dubl., L.R.C.S.Edin., L.K.Q.C.P.I., Stillington.
Harris, William, M.R.C.S.Eng., L.S.A.Lond., M.R.C.P.Edin., F.R.C.S.Edin., Hellesdon, Norwich.
Hayman, Charles Augustine, L.R.C.P.I., L.R.C.S.I., L.M.I., Clifton, Bristol.
Lacey, Thomas Warner, L.S.A.Lond., M.R.C.S.Eng., L.R.C.P. Lond., Woolwich.
Powell, Henry William FitzGerald, L.F.P.S.Glasg., L.R.C.P.Edin., F.R.C.S.Edin., London.
Reid, Thomas Whitehead, F.R.C.P.Edin., Canterbury.
Thomson, James Stitt, F.R.C.P.Edin., F.R.C.S.Edin., Dalkeith.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following gentleman having passed the necessary examination has been admitted a Fellow of the College:—

Brooke, James Stuart, L.R.C.S.I., &c.

The following gentleman having passed the necessary examination has been admitted a Licentiate of the College:—

Jones, William Arthur, L.S.A. Lond.

MEDICAL MAGISTRATE.—The Lord Chancellor has added the name of Mr. J. Goodwin Shea, F.R.C.S.Irel., to the Commission of the Peace for the borough of Chesterfield.

THE SOUTHAMPTON INFECTIOUS HOSPITAL.—It is not at all events general for the inspectors of the Local Government Board to publicly express the conclusion at which they have arrived at the end of an inquiry, but the Corporation of Southampton had a strong case for and practically no opposition to their scheme for an infectious hospital to supplement the present accommodation in the Small-pox Ship and the West Quay Hospitals. They asked permission to borrow a sum, estimated at about £2000, to purchase a site of ten acres for the buildings, but the actual price has not been fixed, for several interests being affected in the title to the land the matter has to go to arbitration. The land is high and the soil gravelly and easy to be drained. The present land hospital consists of two old houses scarcely worth repair and an iron addition thereto, while the nurses are not separated from the patients. The ship, of course, is reserved for small-pox patients, and Mr. Harris once more recalled a severe lesson to Southampton some few years ago, when no less than 135 cases were traceable to one imported small-pox patient. The vessel is, in fact, a port sanatorium. The new buildings will, it is thought, take eighteen months to erect, and the inspector disposed of the only serious objection—the carriage of infectious cases through a populous district—by remarking that it had been shown that with proper precautions there was no danger from this practice to the public health; and at the close of the inquiry Dr. Bruce Low said it seemed that the necessity for the purchase of this particular site had been shown, and it would appear from the evidence that it would be an economical scheme. He should report accordingly.

MR. ROBERT HARTLEY, medical officer of health to the Pemberton Urban District Council, has been elected a member of the County Council of Lancashire.

NATIONAL ORTHOPÆDIC HOSPITAL. — At the National Orthopædic Hospital, Great Portland-street, there were last year 205 in-patients and 1188 out-patients.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—The Central London Ophthalmic Hospital was partially closed for several weeks last year on account of repairs to the building. The annual report shows that during the year there were 170 in-patients and 9521 out-patients. The receipts were £887, of which the small payments made by patients amounted to £456.

SOUTH DEVON AND EAST CORNWALL HOSPITAL.—The annual report of the South Devon and East Cornwall Hospital at Plymouth shows that during the last year 1152 patients were admitted and 75 deaths occurred; there were also 2274 out-patients. The expenditure exceeded the income by £190 and there was at the bank an overdraft of £801. The Earl of Mount Edgcumbe presided at the annual meeting.

SEAMEN'S HOSPITAL SOCIETY. — The annual meeting of the Seamen's Hospital Society was held at the Mansion House, Sir Donald Currie, M.P., presiding. The report showed that mainly through the receipt of a legacy of £2150 the receipts had been sufficient to cover the expenditure. Last year there were 18,293 patients, one-half of the in-patients being foreigners. The chairman read a list of subscriptions amounting to £675, which he had received, and said that he himself would contribute £1000. A vote of thanks to the contributors was proposed by the United States Ambassador and carried unanimously.

BIRMINGHAM GENERAL DISPENSARY. — The annual report of the Birmingham General Dispensary showed that the total number of patients admitted last year by tickets at the various branches was 32,774. Dental cases and accidents continued to be treated without tickets being obtained, and of these cases there had been 5091, bringing up the total number of patients to 37,865. The total income during the year was £10,770 and the expenditure £10,355, leaving a balance of £415 to be carried forward. The grant of the Hospital Saturday Fund was £900 to the general fund and £250 to the relief fund. The average cost of the patients was 3*s*. 9*d*.

ROYAL FREE HOSPITAL.—The annual report of the Royal Free Hospital showed that the patients treated during 1895 were largely in excess of the numbers recorded in 1894. More than 150 students of the London School of Medicine for Women received instruction in the wards, and 25 of them had become qualified to practice. The total expenditure was £10,898 and the income £9124. At the conclusion of the business Mr. Justice Bruce unveiled a marble tablet erected in memory of the late Mr. George Moore, who for twenty years had been a zealous supporter of the hospital.

THE PORTSMOUTH WATER SUPPLY.—The proposal of the Portsmouth Corporation to purchase the undertaking of the local waterworks company has been met with a good deal of difficulty. At the negotiations which were resumed some few weeks ago the chief point of difference between the parties was with regard to the amount of compensation to be paid to the directors and officials of the company; but at a recent conference between the committee of the town council and the directors the latter put forward other and fresh conditions. The directors ask that £10,000 be paid to them and to the auditors as compensation for disturbance; that £4000 be added to the company's reserve to make up the value of the back dividends; and that a year's pay, £4666 in all, be given to each employé of the company. In reply the committee recommend that seven years' fees (£6468) be paid to the directors and auditors, and they are opposed to the back dividends' scheme. They propose to pay seven years' salary to the secretary as superannuation and to retain at their present salaries every other officer of the concern. Arbitration is suggested should the directors fail to accept. This, then, with the addition of the handing over of sufficient Corporation stock to assure to the shareholders interest equal to the full statutory dividends for the water stock, is briefly the price the Corporation offer for the undertaking. The cost is put at just under a million and fifty thousand pounds.

LIVERPOOL INFIRMARY FOR CHILDREN.—The annual report showed that last year there were 1165 in-patients and 14,159 out-patients. The expenditure exceeded the income by £307. The amount received from the Hospital Saturday and Sunday Funds was £636.

ROYAL ISLE OF WIGHT INFIRMARY AND COUNTY HOSPITAL. — At the Royal Isle of Wight Infirmary and County Hospital 428 in-patients were admitted, and twenty-nine deaths occurred during the fifteen months from Oct. 1st, 1894, to Dec. 31st, 1895; there were also in the same period 1922 out-patients. The total income was £3510, and the total expenditure £3291, leaving a balance of £219.

LIVERPOOL LADIES' CHARITY AND LYING-IN HOSPITAL.—The annual meeting of the Liverpool Ladies' Charity and Lying-in Hospital was held on March 18th at the Town-hall, under the presidency of the Lord Mayor (the Earl of Derby). The report showed that during last year 2119 patients were attended at their own homes by the district midwives of the charity, whilst 274 were admitted into the hospital and attended by the nurses acting under the matron. The district medical officers visited 119 of the outdoor cases, and 28 of the hospital cases required the attendance of the hospital medical officers. There had been twenty-five pupils, of whom fourteen were trained as midwives and eleven as monthly nurses. The total expenditure for the year was £2230 and the balance due to the treasurer has now increased to £825.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next examination for the Certificate in Nursing and Attending on the Insane will be held on Monday, May 4th. Particulars can be obtained from the Registrar, Dr. Spence, Burntwood Asylum, near Lichfield.—The spring meeting of the South-Western Division, as we have already announced, will be held at Bailbrook House, Bath, on April 14th, 1896, at 2.30 P.M. Communications: (As by resolution at last meeting) To Consider the Report of the Committee on Criminal Responsibility. Dr. P. W. MacDonald will introduce a discussion on the Nursing Staff in Asylums. Dr. R. S. Stewart will read notes on the Special Reports and Certificates required by Section 38 of the Lunacy Act, 1890, and Section 7 of the Act of 1891. There will be a dinner provided at the Grand Pump Room Hotel at 5 P.M., charge 5*s*. each, exclusive of wine.

LITERARY INTELLIGENCE.—Recent French and German works and new editions announced by Messrs. Williams and Norgate include a second edition of the "Traité des Methodes Techniques de l'Anatomie Microscopique," by Bolles-Lee and Henneguy; a sixth edition of Gegenbauer's "Lehrbuch der Anatomie des Menschen"; Bollinger's "Atlas und Grundriss der Pathologischen Anatomie" (Part 1, Circulationsapparat, Lymphdrüse, Milz- und Schilddrüse); Heitzmann's "Descriptive und Topographische Anatomie des Menschen" (Parts 1 and 2, Bones, Joints, and Ligaments); Lewin's "Beiträge zur Dermatologie und Syphilis"; Von Niessen's "Der Syphilis-bacillus"; third edition of Bresgen's "Krankheits- und Behandlungslehre der Nasen-, Mund- und Rachenhöhle"; "Abba's Manuale di Microscopia e Batteriologia applicate all' Igiene," "Oeller's Atlas der Ophthalmoscopie (Part I.)"; "Londe's Photographie Moderne"; and "Miethe's Lehrbuch der Praktischen Photographie." The same firm publish Murray's treatise on the Deep and Shallow-water Marine Fauna of the Kerguelen Region of the Great Southern Ocean and An Account of the Crustacea of Norway, by Professor G. O. Sars, of which Vol. I. on the Amphipoda appeared last year, and Vol. II. on the Isopoda is in preparation. Of special interest at the present time are Roentgen's "Photographiën einer neuen Art von Strahlen," and Wünschmann's "Die Rœntgenschen X-Strahlen, gemeinverständlich dargestelt."—The Rebman Publishing Company (11, Adam-street, Strand, W.C.) have ready for immediate publication a new work, entitled "Water and Water-supplies," by Dr. J. C. Thresh.—Mr. Young J. Pentland has in preparation a Text-book of Physiology, to be edited by Professor Schäfer of University College, and containing contributions by Professors Halliburton, Gamgee, Burdon Sanderson, Gaskell, Langley, Sherrington, McKendrick, Haycraft, and others.

Digitized by Google

PRESENTATION.—Mr. J. F. Shanahan, L.R.C.P., L.R.C.S. Irel., has been presented by the Limerick Royal Irish Constabulary with a valuable dining-room clock and two bronze mantel figures. The clock bore the following inscription: "Presented to Dr. J. F. Shanahan by the Limerick Royal Irish Constabulary, on his marriage, as a mark of their esteem and in recognition of his ability and unremitting attention as their surgeon."

FOOTBALL CASUALTIES.—While playing a match on Saturday last for Bedminster against the Eastville Rovers, a young man sustained injuries to his head from which he died on the following day.—A player (a factory worker at Bessbrook, near Newry) died at Dungannon on the 29th ult. from injuries to his head received in a match on the previous Saturday.—While playing a game on the 28th ult. in the Anderton-road, Sparkhill, a young man aged twenty-seven fractured his leg and was taken to the General Hospital, Birmingham.

THE DIFFUSION OF SMALL-POX AT GLOUCESTER.—Affairs at Gloucester have entered upon a different and a more serious phase during recent days. Not only have the cases newly arising developed in larger numbers than at any former time in the course of the epidemic, but this has happened at a time when seasonal circumstances of one and another kind are in favour of a still further augmentation of attacks. True it is that the altered attitude of the guardians towards the enforcement of primary vaccination has made changes which may have an appreciable effect on the future of the disease in Gloucester if matters are properly handled. The chances of this being done are greatly increased by the fact that the Local Government Board have sent their assistant medical officer, Dr. Parsons, to the city for the purpose of showing how the newly-acquired life of the compulsory clauses of the Vaccination Acts may be spent to the best advantage in the interests of the unvaccinated portion of the community. This kindly action on the part of the Local Government Board shows still more the wisdom of the step taken by the guardians, as it would have been manifestly absurd of the Board to have intervened in any way whilst the vaccination authority was bent on remaining inactive. On the other hand it is pleasing to note the alacrity with which the Board have stepped into the breach the moment it was deemed possible that the experience of their experts would avail to help the disease-stricken city. Whilst Dr. Parsons is thus busy assisting the authority in their efforts to stamp out the epidemic, Dr. Coupland, on behalf of the Royal Commission on Vaccination, is, we are glad to learn, engaged in studying the facts as to vaccination in relation to small-pox, a matter which is worth a great amount of pains at the present moment when the Commission are apparently approaching the completion of their seven years' sittings.

Parliamentary Intelligence.

CURRENT NOTES.

The Meat-supply for the Army.

FROM time to time recently questions have been addressed to the representatives of the War Office with regard to the quality of the meat supplied to different branches of the Army and to the proportion of foreign-grown meat allowed in the contracts, and it is understood that the Secretary of State for War has decided to make the whole subject a matter of special inquiry.

Shops Early Closing Bill.

Sir John Lubbock's Bill for the earlier closing of shops has emerged from the Grand Committee on Trade in very much the same condition as when introduced. The advocates of the voluntary closing movement proposed many amendments, but were successful with only a few and these unimportant. One alteration made is to the effect that the application by two-thirds of the shopkeepers to the local authority shall mention the hour which they desire to see inserted in the order, and among the shops expressly excluded from the operation of the Act are those in which hot cooked provisions are sold.

HOUSE OF COMMONS.

FRIDAY, MARCH 27TH.

Butter Adulteration.

Mr. Walter Long, President of the Board of Agriculture, in reply to a question by Mr. Kearley, said that during February 170 samples of imported butter were taken, of which 15, or 8·8 per cent., were found to be adulterated.

The Outbreak of Small-pox at Gloucester.

Mr. Radcliffe Cooke asked the President of the Local Government Board whether he was aware that small-pox was increasing in Gloucester at the rate of sixty fresh cases a week, the mortality being especially great among children, and that in one school out of forty children attacked no less than twenty-six died; whether he could say how many deaths were of unvaccinated and how many of vaccinated persons; and what steps, if any, were being taken to check the ravages of the disease.—Mr. Chaplin replied that the number of cases of small-pox notified to the Local Government Board during the four weeks ended March 21st was 414, 155 being in respect of the last-mentioned week. No details as to particular schools or as to the proportion of deaths amongst vaccinated and unvaccinated persons were as yet available. He was informed by the town council that they had done all that they could in the way of hospital isolation and disinfection to check the spread of the disease, but he was advised that the only effective means of controlling the extension was the adoption of a general system of vaccination and revaccination. He was informed by the guardians that every facility was being afforded by them for vaccination and revaccination, that both operations were being carried out very largely, and that the guardians at their last meeting resolved to enforce the Vaccination Acts, which, he understood, had been in suspension for the last nine years.

Illness in Poor-law Schools.

Mr. Chaplin, in answer to a question by Mr. Drage, said that scarlet fever had been prevalent in the Forest Gate school since August, 1895. During the last five months of the year seventy cases occurred. It was of an extremely mild type and many of the cases were so slight that their nature was difficult to recognise. He was glad to be able to state that there had been no death from the disease. There were twenty-three cases of diphtheria in 1895 in the Poor-law schools of the metropolitan district. Dr. Downes, the Inspector of the Board, stated that so far as he could judge from the best available data diphtheria during 1895 was about three times more rife among metropolitan children of school age not resident in Poor-law schools than it was among the children resident in such schools. According to a return made in the present month there were 641 cases of ophthalmia under treatment or observation in metropolitan Poor-law schools. The number for the corresponding period of 1895 was 709. Dr. Downes informed him that the cases were chiefly those of catarrhal ophthalmia or of granular lids, and that he was not aware that there had been any outbreak of the more serious form of purulent ophthalmia during the year.

MONDAY, MARCH 30TH.

Venereal Disease in the Indian Army.

Lord George Hamilton, in reply to a question by Mr. Duncombe, said that the growth of venereal disease in the Indian army consequent upon the abolition of the previous protective measures against it had been a source of great concern to the Government of India, who reported that it prevails "to such an extent as to constitute a most serious cause of inefficiency in the army." The Government of India were considering what instructions or regulations it might be possible for them to issue to mitigate the scourge without infringing the restriction imposed upon them by the resolution passed by the House upon the subject.

Dissection of Rabbits by Girls.

Colonel Lockwood asked the Vice-president of the Committee of Council on Education whether he had become acquainted with the purport of statements lately published in Birmingham to the effect that a class of young girls at the Waverley-road Board Schools were made to dissect the bodies of rabbits; were these operations enjoined by the Government Inspector; if so, were they sanctioned by the department as a necessary part of the education of girls; was the kind of teaching involved to be continued; and would he see that the use of diagrams as illustrations were substituted for such experiments.—Sir John Gorst said, in reply, that the dissection in question was performed by some sixteen girls, not in an elementary school, but in the advanced course of the Organised Science School. Physiology was a compulsory subject in this course and the regulations of the Science and Art Department required a practical acquaintance by the use of a microscope with the minute structure of the several tissues and organs. None of the girls were under fourteen and nearly all were over fifteen. The clerk of the Birmingham School Board had stated that the actual dissection was nothing more than any girl would necessarily perform in preparing a rabbit for stewing and had probably been done without remark in most cookery kitchens.

The Alleged Increase of Lunacy.

Mr. Hobhouse asked the Secretary of State for the Home Department if he had communicated further with the Lunacy Commissioners, and if he was now prepared to make a further statement as to the causes of the recent great increase of lunacy and the operation of the 4*s.* grant or to institute an inquiry into the subject.—Sir Matthew White Ridley replied: I have had no direct communication recently with the Lunacy Commissioners on the subject, but I have suggested to the Lord Chancellor, under whose jurisdiction they are, that in view of the interest that is being taken in the question, it might be desirable to follow the precedent set by the Irish Government and direct the Commissioners, or some of them, to make special inquiries as to the causes of the increase of lunacy and embody their conclusions in the next annual report or in a special paper to be laid on the table of the House.

Medical Examiners in Ireland.

Mr. William Johnston asked the Chief Secretary to the Lord-Lieutenant of Ireland, in view of the fact that the three Queen's Colleges in Ireland sent up for the medical examinations of the Royal University at least three times as many candidates as did the Catholic University School of Medicine, would he explain why one-half of the total number of Fellows and examiners appointed by the Royal University were apportioned to the Catholic University. And, whether there was any clause in the charter or statutes of the Royal University giving this representation to the Catholic University at the

Digitized by Google

expense of the Queen's Colleges of Belfast, Cork, and Galway.—Mr. Gerald Balfour said, in reply, that the charter and statutes of the Royal University of Ireland empower the senate to appoint or employ such examiners as may be necessary, and impose no restrictions as to the persons who may be so employed. He was informed by the secretaries to the University that it has been the usual practice, ever since its foundation, to appoint as far as possible one half of its ordinary examiners from amongst the professors of the endowed or Queen's Colleges, and the other half from the professors of unendowed colleges, this practice had been followed in the medical as well as in the arts faculty.

The Vaccination Question.

Mr. Channing asked the President of the Local Government Board whether inquiries had been made by the Royal Commission on Vaccination into outbreaks of small-pox at Warrington, Leicestershire, and other places; when the results of those inquiries would be made public; and what opportunities would be given to those who had taken local interest in the matter to represent any observations thereon to the Royal Commission before it presented its final report?—Mr. Chaplin replied that he had made inquiry and he was informed that it was the fact that inquiries had been made by the Commissioners into these outbreaks. When the results of the inquiries would be made public he was unable to say, but he was advised that the Commissioners could not undertake to delay the presentation of the final report until the publication of the results. The last question was one which ought to be addressed to the Commissioners, he having no authority to interfere.—In reply to a question by Colonel Russell on the same subject, Mr. Chaplin said that he had communicated with the Commission, and he had been informed that it was impossible to name a date when the Commission's report would be laid upon the table. The Commissioners had been for a long time engaged on its preparation, and they hoped it would not be long before it was presented. The Local Government Board had already sent Dr. Sidney Coupland to Gloucester to inquire into and report upon the epidemic there.

IN COMMITTEE.

Food Products Adulteration.

The Select Committee of the House of Commons on the Adulteration of Food Products held its final meeting for the examination of witnesses on Wednesday, March 25th,

Mr. Richard Bannister, Government Analyst at Somerset House, said that statements had been made by the representative of the Society of Public Analysts to the effect that the Somerset House authorities were incompetent for their work, and he desired to give evidence to prove that such was not the case. Long before the establishment of public analysts a large part of their duties had been performed, and performed with success, by the Inland Revenue Commissioners and their staff. They had bestowed very great attention upon tea and coffee, and upon spirituous drinks, vinegar, arrowroot, and articles of that kind, and the results of their work would be found in the records of the department and in blue-books. He maintained that the department had not been backward in scientific research and that its chemical and other scientific knowledge was well up to date. In five years there had been 933 prosecutions in connexion with excisеable articles. The cases dismissed were 14 in number, and the total amount of the fines imposed was £17,203, and he might add that no case was lost through faulty expert evidence. When the Food and Drugs Act came into operation in 1875 the department obtained a large number of carefully-selected samples of pure milk and butter and had them analysed in order to secure reliable data, and the results of the analyses were published in due course. He might say that no effort had been spared by the board or their chemical staff to carry out their duties in a manner entitling them to public confidence for zeal, thoroughness and impartiality. The most fruitful source of discussion with regard to the proper carrying out of the Food and Drugs Act was the limit or standard to be applied to milk, and he asserted that some analysts applied too high and rigid a standard and did not make sufficient allowance for natural variations in the milk. Mr. Bannister then discussed in detail a number of cases quoted by the representative of the Society of Public Analysts. Having done this, he said, in reply to the chairman, that it would certainly be most desirable that the authorities of Somerset House and the Society of Public Analysts who were engaged in the same class of work should, as far as possible, have uniform standards and limits. It was desirable that they should agree, but they could not agree. The present friction was considerable and greatly to be regretted, but he might say that with some of the public analysts in the country they had no difficulty whatsoever. He was not much in favour of fixed standards, but if they were to have a standard for milk it should be laid down in an Act of Parliament.

The Chairman (Mr. T. W. Russell) said that although the Committee had been sitting during three sessions of Parliament they were still being inundated with applications to be heard, and the Committee had decided to close their inquiry after hearing Mr. Beck, the solicitor of the Metropolitan Grocers' Association. They were of opinion that they would then have sufficient evidence with which to proceed to the consideration of their report.

Mr. Beck was then examined. He expressed the opinion that if properly administered and if amended in a few particulars the present Adulteration Acts were sufficient. In conducting prosecutions he found among magistrates a prejudice against traders undertaking prosecutions and among local authorities a distinct tendency to discourage information from private individuals. With regard to the sale of margarine as butter it appeared to him wise that there should be a minimum penalty from a second offence, and that with certain safeguards it should be possible in flagrant cases to impose imprisonment without the option of a fine.

The Committee have arranged to meet on April 14th to consider on what lines their report should proceed.

VACCINATION GRANT.—Mr. Horatio E. Walker, M.R.C.S. Eng., has again been awarded the full vaccination grant for the central district of the Corwen Union, North Wales.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ALCORN, R. G., L.R.C.P. Edin., L.R.C.S. Irel., has been appointed Government Medical Officer and Vaccinator for Maitland, New South Wales.

ALLEN, W. T. D., M.B., B.S. Irel., has been appointed Assistant Medical Officer for the Parish of Liverpool Workhouse.

ANDERSON, R. S., M.D., C.M. Edin., has been appointed Medical Officer by the Spennymoor Urban District Council.

BAIN, J. G., M.B., C.M. Glasg., has been appointed Medical Officer for the No. 2 District of the Wellington (Somerset) Union, vice A. Lyndon, resigned.

BARKER, W. H., M.R.C.S. Eng., L.R.C.P. Edin., has been appointed Acting Medical Superintendent of the Ararat Lunatic Asylum, Australia.

BLAXLAND, H., L.R.C.P. Lond., M.R.C.S., has been appointed pro. tem. Deputy-Inspector-General of the Insane, New South Wales.

BROWNE, V. E., M.B. Dub., L.R.C.S. Irel., has been appointed Health Officer for Rosedale Shire, Dennison and Rosedale Ridings, Victoria Australia.

CLAPHAM, G. P. P., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Assistant Medical Officer for the Workhouse of the Parish of Liverpool.

CROSS, G. F., M.B., B.S., has been appointed Medical Officer of Health to the Downham Rural District Council, vice F. W. Kirkham, resigned.

CROWTHER, E. L., M.D. Aberd., L.R.C.P. Edin., M.R.C.S. Eng., has been appointed Honorary Medical Officer to the General Hospital, Hobart, Tasmania, vice E. O. Gibbin.

DENSHAM, ASHLEY, M.R.C.S., L.R.C.P., L.D.S., has been appointed Assistant Dental Surgeon to the Dental Hospital of London, Leicester-square.

DUNN, E. D., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Public Vaccinator for the district of Nelson, New Zealand.

FENTEM, THOS., M.B., C.M. Edin., B.Sc. (Public Health), has been reappointed Medical Officer for the North Division of the Bakewell Rural District.

FOREMAN, JOSEPH, L.R.C.P. Edin., M.R.C.S. Eng., has been appointed Government Director of Sydney Hospital, New South Wales.

GORMLEY, J. W., L.K.Q.C.P., L.R.C.S. Irel., has been appointed Health Officer for North Ovens Shire, Victoria, Australia.

GOUGH, H. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Northwich Urban Sanitary District, vice J. M. Fox.

GRAHAM, JAMES, M.D. Edin., has been appointed a Director of the Prince Alfred Hospital, Sydney, New South Wales.

HARVISON, W. S., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Government Medical Officer and Vaccinator for Cooma, New South Wales.

HUGHSTON, R. W., M.B., Ch.B. Melb., has been appointed Health Officer for Fern Tree Gully Shire, Victoria, Australia.

KNOX, JOHN, M.D. Aberd., L.R.C.S. Edin., has been reappointed Medical Officer of Health for the South Division of the Bakewell Rural District.

LOVEGROVE, THOS. H., M.R.C.S. Eng., has been appointed Coroner for Perth, Freemantle, and Swan districts, Western Australia.

MORRIS, H. G., M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer to the Hockley Provident Dispensary, Birmingham (Sands Cox Trust).

NATTLE, W. R., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Officer at Mafeteng, Basutoland, South Africa.

NORRIS, W. P., M.B., Ch.B. Melb., has been appointed Health Officer for Romsey Shire, Victoria, Australia.

PERN, E. C., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Workhouse and the Droxford and Soberton Sanitary District of the Droxford Union, vice A. H. Goodwyn, resigned.

PLAYER, C. R., M.B., Ch.B. Melb., has been appointed Acting Medical Superintendent to the Sunbury Lunatic Asylum, Victoria, Australia.

RANDOLPH, C., M.R.C.S., L.R.C.P., L.M. Edin., has been appointed Medical Officer for the No. 5 District of the Wellington (Somerset) Union, vice H. W. Randolph, resigned.

ROTH, B., J.P., F.R.C.S. Eng., has been appointed Surgeon to the Orthopædic Department of the Royal Alexandra Hospital for Sick Children, Brighton.

SALTER, C. E., M.D. Lond., B.S., L.R.C.P., F.R.C.S., has been appointed Honorary Surgeon to the Scarborough Hospital.

SANTI, PHILIP R. W. DE, F.R.C.S., has been appointed Assistant Surgeon (vice C. Stonham) and Aural Surgeon to the Westminster Hospital.

SMITH, W. T., M.R.C.S., has been reappointed Medical Officer of Health by the Lepton District Council.

THOMAS, J. T., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Camborne Urban Sanitary District, vice R. Erskine, resigned.

THOMSON, J. A. M., L.R.C.P. Irel., L.M., L.R.C.S. Irel., has been reappointed Medical Officer of Health for Bradford-on-Avon.

THORP, S., M.R.C.S., has been appointed Medical Officer for the Fourth Sanitary District of the Hexham Union, vice A. H. Hoffman, resigned.

WHITLING, H. T. M., M.B., B.S. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Third Sanitary District of the Market Harborough Union, vice H. H. Lovell, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BATH URBAN SANITARY AUTHORITY.—Medical Officer of Health. Salary £200 a year.

BELGRAVE HOSPITAL FOR CHILDREN, 77, Gloucester-street, London, S.W.—Dispenser. Salary £50 per annum. Also Clinical Assistant.

CITY OF BIRMINGHAM.—Deputy Medical Superintendent for the City Hospital, Little Bromwich, unmarried. Salary £175 per annum, with residence, rations, and attendance. Applications to the Clerk to the Health Committee, Council House, Birmingham.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Pathologist. Salary 100 guineas per annum.

DENTAL HOSPITAL OF LONDON AND LONDON SCHOOL OF DENTAL SURGERY, Leicester-square, W.C. — Lecturer on Mechanical Dentistry.

DR. STEEVENS' HOSPITAL, Dublin.—House Surgeon for two years. Salary £100 per annum, with apartments, fire, and light.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—Resident Medical Officer. Salary £80 per annum, with board and residence.

HEREFORD COUNTY AND CITY ASYLUM. — Medical Superintendent. Salary £400 per annum, with furnished house, coals, gas, vegetables, and washing. Applications to Chairman, Asylum Committee, Shirehall, Hereford.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.—House Physicians. Also Clinical Assistants to the Out-patient Department and Clinical Clerks to the In-patient Physicians.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Bloomsbury.—Surgical Registrar, for one year, an honorarium of £40 being voted at the expiration of that term.

KESTEVEN AND GRANTHAM DISTRICT ASYLUM. — Resident Medical Superintendent. Salary £300 a year, with rations, coals, light, and washing. Applications to the Clerk to the Visitors, Stamford.

LIVERPOOL NORTHERN HOSPITAL.—Assistant House Surgeon. Salary, £70 per annum, with residence and maintenance in the hospital.

MANCHESTER ROYAL EYE HOSPITAL.—House Surgeon. Salary £70 per annum, with residence, board, and washing.

MIDDLESEX HOSPITAL, W.—Honorary Senior Surgeon.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Resident Medical Officer for six months. Salary £30 per annum, with board, attendance, and washing.

OWENS COLLEGE, Manchester.—Junior Demonstrator in Physiology.

PADDINGTON-GREEN CHILDREN'S HOSPITAL, W.—House Physician and House Surgeon for six months. Salary at the rate of £50 per annum, board and residence.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—Resident Medical Officer for six months. Salary at the rate of £100 per annum, with furnished apartments, board, and washing.

RUPTURE SOCIETY.—Surgeon. Applications to Mr. C. Taylor, 27, Great James-street, Bedford-row, London, W.C.

SOCIETY OF APOTHECARIES.—Examiners. Applications to the Clerk to the Society, Apothecaries' Hall, Blackfriars.

SURREY DISPENSARY.—Obstetric Physician and a Surgeon. Honorarium in each case 50 guineas per annum. Applications to the Secretary, 53, Borough High-street, Southwark.

Births, Marriages, and Deaths.

BIRTHS.

BLAIKIE.—On March 29th, at Minto-street, Edinburgh, the wife of R. H. Blaikie, M.D., F.R.C.S. Edin., of a daughter.

HOLMES.—On March 29th, at Ferndale, Woburn Sands, Beds, the wife of T. D. Holmes, M.D. Edin., of a daughter.

SMITH.—On March 29th, at Brook-street, Grosvenor-square, the wife of Dr. Pye Smith, of a son.

STOCKEN.—On March 28th, at Connaught-road, Harlesden, the wife of Arthur P. Stocken, L.D.S., of a son, stillborn.

MARRIAGES.

BENSON—SIMMONDS.—On March 26th, at St. Paul's, Herne-hill, Henry Mitchell Benson, M.B., C.M. Edin., eldest son of John Benson, Broomhill, Sheffield, to Stella Theodora, third daughter of the late Henry Simmonds, Aylesford House, Herne-hill.

SHUTER—TIPPETT.—On March 26th, at the Parish Church, Chiswick, George Percy Shuter, M.A., M.B., B.C. Cantab., D.P.H., of Oaklands, Chiswick-lane, W., to Ellen Frances Tippett, of Cleveland House, Chiswick, second daughter of G. F. Tippett, of Bromley.

STEPHEN—HETT.—On March 26th, at St. Stephen's, Westminster, by the Rev. J. Rogers, Vicar of Gatton, Surrey, assisted by the Rev. H. Twining, Vicar of St Stephen's, John Stephen Stephen, M.B., C.M., Edinburgh, and of Gallowcrook, Elgin, to Emmie Cundell, second daughter of J. Hett, Esq., Headlam Hall, Darlington.

DEATHS.

COPELAND.—On March 25th, at Staindrop, William Copeland, M.R.C.S., aged 80.

MONCKTON.—On March 26th, at Maidstone, David Henry Monckton, M.D. Lond., aged 67.

TUCKER.—On March 29th, at Glaslyn, St. Leonards-on-Sea, John Dunning Tucker, aged 67.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the second half-yearly volume for 1895 was given in the issue of Dec. 28th. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1895 are now ready. Bound in cloth, gilt lettered, price 18*s*.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*.; by post, 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

CHARGES OF EXTRAVAGANCE AGAINST THE ASYLUMS BOARD.

THE Islington vestry, which is represented by Mr. Elliott in the Metropolitan Asylums Board, has very properly declined, notwithstanding strong and almost plaintive pressure from Mr. Elliott and his friends, to express any opinion on his position in regard to the charges which he has seen fit to bring against the Board in connexion with the payment of large sums for sites for hospitals. The public admires any man who has the courage to push such charges to a demonstration. But to make them and then to flinch from carrying them through is a very different matter. The whole system of the Board, its efficiency, its wholesale admission of patients of all sorts and conditions with "no restriction or regulation" such as was contemplated in the Acts by the Local Government Board, constitute a big question for very serious inquiry of which we see little chance at the present time. The Board has given every opportunity of inquiry to Mr. Elliott.

"THE POISON OF THE PRIMULA."

To the Editors of THE LANCET.

SIRS,—In answer to your inquiry on the above subject in THE LANCET of March 28th I beg to say that about two months ago a young man, a gardener, consulted me about a very severe attack of inflammatory eczema, confined to the right forearm and back of the right hand. He said he had been handling primula obconica and that he had had a similar, though less severe, attack of the same kind in the previous autumn from the same cause. I have made several inquiries amongst those interested in gardening in this district, and it seems to be a well-recognised fact that primula obconica at any rate produces in many cases artificial eczema of varying degrees of severity. I have not obtained evidence against any other variety of primula in this respect, but as the whole order of primulaceæ are more or less noted for their acridity it is very likely that other members of the order produce skin eruptions. Primula obconica is in flower all the year round, and it would be interesting to know if the poison be virulent throughout the year or only at particular seasons. The poison is distilled from the hairs which may be seen thickly covering the leaves and other parts of the plant. Gardeners, amateur and professional, should know of this possible source of discomfort and should always have their hands and arms covered when handling plants of the order primulaceæ. The eczema in my case quickly subsided by local application of the following lotion: Acidi carbolici, acidi boracici, āā 3 ss.; calaminæ præparatæ, 3 iv.; magnesiæ ustæ, 3 ii.; glycerini pur., 3 ij.; aquæ destillatæ ad ℥ viii.

I am, Sirs, yours faithfully,

LOUIS E. STEVENSON, M.B. Camb., &c.

Temple Sowerby, Westmorland, March 30th, 1896.

To the Editors of THE LANCET.

SIRS,—About five years ago I had under my care a lady who suffered from recurring attacks of an erysipelas-like character. She had suffered more or less for twelve months. As a rule the attacks came on suddenly, her whole face would swell, including the eyelids, so that she could no longer see, and large blisters formed over the cheeks and chin. The dorsal aspect of the hands and forearms were also affected, but in a much slighter form. She had never had erysipelas or anything resembling it previously to the beginning of this attack, and no known cause had been discovered. She was usually confined to bed for a few days and then quite recovered, but whenever she came downstairs a few minutes — sometimes ten — were sufficient to close her eyes, &c., so that she had to retire at once. I at last discovered that when she came downstairs the first thing she usually did was to take away the decayed foliage, flowers, &c., from a very fine specimen of primula obconica. I removed the primula and the patient since then has never suffered from primula erysipelas. I have seen one or two cases since in gardeners, but confined to their hands and forearms, but have never seen such a severe case as described above.

I am, Sirs, yours truly,

THOS. A. F. HOOD.

Ivy Bank, Blairgowrie, N.B., March 28th, 1896.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 28th you say you would like to hear of anyone having had under his care a patient suffering from the handling of primulas. I met with such a case in June last. A middle-aged lady consulted me with reference to a rash affecting the dorsal aspect of the hands and fingers. It was not erysipelatous in character, but more like a dry eczema and attended with a good deal of pruritus. She had been under the care of a dermatologist in London, but soon after she returned home the condition recurred. As I noticed that the rash stopped abruptly, where the wrist became covered by the dress, and also failing to find any diathetic cause for the condition, the treatment of which was not very satisfactory, it occurred to me, as I had heard of the effects of the primula in this way, to ask her if she was in the habit of handling these plants. She at once said she had several pots containing plants of primula obconica with which her hands were often in contact. I advised her to leave off all medication and to keep her favourites at a respectful distance. She did so, and in about ten days returned to say that my surmise was evidently correct, as she was quite free from her complaint.

I am, Sirs, yours faithfully,

Hull, March 30th, 1896. GEO. F. ELLIOTT.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 28th you refer to cutaneous irritation from primulas, and inquire if other instances are known. I may say that I have seen two well-marked cases of irritation of the fingers and dorsum of both hands from this cause. The first case which I saw some three years ago was that of a gardener who had been potting or repotting primula obconica for two or three days previously. The dorsum and fingers of both hands were the seat of a red raised rash and the skin of the fingers in some places had become abraded and the surface wept slightly. The other case was in a gentleman who had been potting primulas. The rash was similar to that seen in the first case, but was not so marked, and the right hand was more affected than the left. The irritation in both cases was great, but soon yielded to oleate of zinc ointment and the wearing of gloves when handling the plants.

I remain, Sirs, yours truly,

Halifax, March 28th, 1896. PRIESTLEY LEECH.

THE AERIAL CONVECTION OF INFECTIOUS DISEASE.

To the Editors of THE LANCET.

SIRS,—In times gone by cholera was always believed to be a visitation of Providence; a cholera cloud was constantly talked about and the germ-laden air was supposed to affect one spot and pass over another. But we now laugh at these notions as out of date; at the same time, this apparently does not prevent us from falling back upon this identical method of explaining the spread of other infectious diseases. When we cannot find out some clear cause for some particular outbreak of zymotic disease we say it is due to the atmosphere; the same as when we are unable to explain some peculiar chemical action we say it is due to catalysis. But why, after all, should we discard certain reasonable methods of explanation and fall back upon mere suppositions? For instance, why should we put forward the idea as regards small-pox, that the occurrence of cases around small-pox hospitals is due to aerial convection, when we know that nurses and attendants are constantly going into the surrounding districts and in all probability carry some infection with them? Because the germs of malaria are wafted about by the air that is no reason of itself why animal poisons should be distributed in the same way. The soil would say destroys the animal germs, but keeps alive those peculiar to marshy districts. If it be asserted that both vegetable and animal poisons get disseminated in the same way, then a belt of trees round infectious hospitals should be equally as efficacious as they are round low-lying marshy areas. But will anyone be got to say that they will be? My own belief is that the air is destructive to animal but not to vegetable poisons.

I am, Sirs, yours faithfully,

Surbiton, March, 1896. F. P. ATKINSON.

P.S.—From Dr. Manson's lectures on malaria it would appear that even the idea of the aerial convection of the malaria germ may soon be swept away.

H. F. (Southernhay).—It seems to us, from our correspondent's account, that X. ought to decline to attend the patient. An interview between A. and X. would ensure amicable relations, whatever their mutual decision.

Mr. E. Curtin.—The circular is discreditable, but we cannot find by the current Register or Directory that it is issued by a qualified medical practitioner.

Devon.—(1) Our correspondent's first duty is towards his patient. (2) Certainly not.

THE STRENGTH OF THE HUMAN JAW.

THAT the muscular strength of the jaw in man, notwithstanding the remoteness of his reputed descent from simian ancestors possessed of gigantic maxillæ, has by no means dwindled into insignificancy is a matter of common knowledge. Readers of "Alice's Adventures in Wonderland" will remember how Father William explained his prowess as a trencherman to his son:—

> "'In my youth,' said his father, 'I took to the law,
> And argued each case with my wife;
> And the muscular strength which it gave to my jaw
> Has lasted the rest of my life.'"

But it appears that an American dentist claims the honour of being the first to endeavour to determine the exact amount of such muscular strength by means of a special dynamometer of his own invention, with which he has carried out a series of experiments on no fewer than 500 persons of both sexes and various ages. It has been argued, with some show of reason, that owing chiefly to the introduction of knives and forks and the consequent partial disuse of the teeth as agents for disruption the jaw-bones of civilised peoples are gradually undergoing attenuation, the shrinking process being further aided by the abbreviation of mastication which has attended on the aspirations towards tenderness of modern cooks; but we are not aware that any serious attempt has ever been made by ethnologists to investigate the truth or falseness of this theory. The subject is nevertheless one to which considerable interest attaches, and the American record, if authentic, should prove valuable to future investigators. It seems that the owners of the 500 jaws were able to exercise therewith on an average a pressure equivalent to about 100 lbs.; but the maximum and minimum, owing to age and other causes, were widely divergent. A little girl aged seven, for instance, could raise the index of the dynamometer to the 30 lb. mark with her incisors alone and to that for 65 lb. with her molars; while a gentleman with an extraordinarily powerful jaw (who happened, curiously enough, to belong to the medical and not to the legal profession) succeeded without apparent effort in exhausting the resources of the indicator with a pressure equal to 270 lb. The sole account of these experiments, which has reached us through a Continental channel, is rather meagre and inconclusive, but doubtless a complete report has been, or will be, published.

"THE BALL-NOZZLE SYRINGE AND ENEMA."

To the Editors of THE LANCET.

SIRS,—With reference to your remarks on the ball-nozzle syringe in THE LANCET of March 21st, we write to say that the improvement suggested by you is being carried out, so that no part has the smallest bit of metal about it, the whole being made entirely of ebonite.

We are, Sirs, yours faithfully,

THE BRITISH-AMERICAN BALL NOZZLE CO.

Oxford-street, W., March 26th, 1896.

E. A. H.—Under these circumstances we know that half a fee has been taken. Whether this is fair or not must differ in different cases. For an opinion on the legal aspect of the case we must refer our correspondent to a solicitor.

L.R.C.S.—Certainly not. The certificate can only be signed by a registered medical practitioner.

"AMBULANCE LECTURES AND MEDICAL ADVERTISEMENT."

OUR paragraph upon this subject has brought us several illustrations of the thing we complained of. We cannot express an opinion on individual instances, preferring to leave it to the taste of ambulance lecturers to decide how far publicity is given to their name, and when it takes an unprofessional form.

M.O.H.—The Infectious Disease (Notification) Act, 1889, is quite clear on the point. Section 3 (*b*) says, "*every* medical practitioner attending or called in to visit the patient" shall forthwith notify. If it were not so, a patient might immediately after the first notification remove, or be removed, into an adjoining district, where he would avoid his infectious sickness being placed under any control. If the district council still refuse the fee, the actual circumstances of the case, with the dates of the two notifications, should be submitted to the Local Government Board and their view be asked. But we have dealt fully with this question and have quoted the decision of the Local Government Board as to it in the last of our series of four articles entitled "Difficulties under the Infectious Disease (Notification) Act, which appeared in THE LANCET of Jan. 19th, 26th, Feb. 9th and 16th, 1895.

Perplexed.—The circumstance mentioned must be regarded as favourable to our correspondent's chances, but scarcely to constitute a claim. Assuming that there is nothing in his relation to the retiring medical officer forbidding his candidature his success should be very probable.

ADVERTISING DENTISTS IN KENSINGTON.

"Dr." Cadwaladr Jones seems to have a warm, if rather injudicious, friend in the editor of *Society*, which on more than one occasion has contrived little paragraphs designed to send patients to him. The following is a specimen which—who could resist?

> "Cloe.—You will find 'Dr.' Cadwaladr Jones an excellent dentist, and very kind and gentle. He knows all about crowns and bridgework, and if he considers it desirable he uses it at reasonable charges. You will find him at 2, Queen's-road, a pretty little house overlooking Kensington-gardens."

Our only difficulty in acquitting Mr. Jones of any responsibility for such paragraphs is their appearance more than once, for presumably a word from him would stop the puff. He must know that the Irish College of Surgeons, whose dental licence he has, would not hold any of its licentiates blameless who sanctioned such paragraphs even by silence.

M.R.C.S. (ambulance) has omitted to enclose his card.

THE CONSULTING-ROOM IN AMERICA.

THE *Maryland Medical Journal* says that Philadelphia is soon to have a large office building which will be known as "The Clinic," and will be occupied exclusively by consulting-rooms for medical men. Cincinnati and New Orleans have such buildings in successful operation, and at New York a similar project is in contemplation.

MADURA FOOT DISEASE IN AMERICA.

IN the *Montreal Medical Journal* for January Adami and Kirkpatrick describe the first indubitable case of mycetoma recorded as occurring in a patient who had never travelled outside the continent of America. The affected limb was after amputation exhibited before the Medico-Chirurgical Society of Montreal.

KITSON *v.* PLAYFAIR AND WIFE.

WE have received a large number of letters on this case from medical men in different parts of the United Kingdom. It is obvious that pending the appeal the case cannot be commented on.

ERRATUM.—Mr. Lennox Browne informs us that he was preceded in his views upon lingual varix by G. Lewin of Berlin, who described it with pictorial illustrations, and attributed to it some importance as far back as 1863.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.).

TUESDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (8th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).

THURSDAY (9th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Great Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (10th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.) Gt. Northern Central (2.30 P.M.).

SATURDAY (11th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (8th).—HUNTERIAN SOCIETY (London Institution).—8.30 P.M. Dr. P. Warner: Notes on a Case of Typhlitis; Mr. Symonds (late President) who operated on the case will also contribute his notes.

THURSDAY (9th).—BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Adjourned Discussion on Ventro-fixation, Ventre-suspension, and Allied Operations, with their results. Mr. Bowreman Jessett: The Importance of Early Diagnosis of Cancer of the Uterus (illustrated by numerous specimens and the results of treatment).

FRIDAY (10th).—WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road, S.E.).—8.15 P.M. Mr. H. Marsh: Recent Progress in the Pathology and Treatment of Diseases of the Joints (illustrated by specimens).

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Mr. R. J. Godlee: Two Cases of Acute Abscess of the Liver.—Dr. S. West: On Albuminous or Serous Expectorations.—Dr. G. N. Pitt and Mr. Arbuthnot Lane: Cranial Cyst of Sarcomatous Origin; no recurrence two years after Operation.—Mr. H. W. Page: Sequel to a Case of Syphilitic Cranial Necrosis recorded in vol. xxviii. of the Transactions; Gumma of Frontal Lobe; Death.—Mr. L. Hudson: A Case of Malingering in a Boy of Eleven.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, W.).—8.30 P.M. Papers:—Mr. J. B. Jessett: A Case of Fæcal Fistula cured by Resection of Small Intestine by Maunsell's Method.—Dr. Thudichum: The Chemistry of the Carbohydrates, with special reference to Diabetes. Pathological specimen by Mr. A. Doran.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FRIDAY (10th).—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Dr. Dundas Grant: Some recently introduced methods for the Diagnosis of Diseases of the Ear.

During the week marked copies of the following newspapers have been received:—*Dudley Herald, Sheffield Telegraph, Newcastle Leader, Hull Daily Mail, Times of India, Norfolk Daily Standard, Rangoon Gazette, Manchester Guardian, Doncaster Chronicle, Pioneer Mail, South Wales Daily News, Montreal Star, Hongkong Weekly Press, Leicester Daily Mercury, Hastings Independent, Newbury Weekly News, Sussex Daily News, Bradford Observer, Wolverhampton Chronicle, Walsall Advertiser, Birmingham Post, Kingston News, Architect, Darwen News, Portsmouth Times, Scotsman, North British Advertiser, Coventry Daily Telegraph, Builder, St. Pancras Guardian, Dundee Advertiser, East Dorset Herald, Liverpool Courier, Westminster Gazette, The Morning, Cork Weekly News, Invention, Electrical Review, Brighton Gazette, Morning Advertiser, The Times, Hertfordshire Mercury, Bedfordshire Times, Local Government Chronicle, Mining Journal, Reading Mercury, City Press, Weekly Free Press and Aberdeen Herald, West Middlesex Standard, Gloucestershire Chronicle, Guy's Hospital Gazette, Surrey Advertiser, Cheltenham Chronicle, Australian Medical Gazette, The Gazette (Montreal), Cornish Telegraph, Chatham News, Public Opinion, Local Government Journal, &c., &c.*

The Hunterian Lectures
ON
INFANTILE SYPHILIS.

Delivered at the Royal College of Surgeons of England on March 23rd, 25th, and 27th,

BY J. A. COUTTS, M.B. CANTAB., M.R.C.P. LOND.,
PROFESSOR AT THE COLLEGE, AND PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN.

LECTURE I.

MR. PRESIDENT AND GENTLEMEN,—In the first place I have to acknowledge my indebtedness to the Council of this College for allowing me to occupy this present position. I feel, however, that I can best fulfil the trust imposed on me by not elaborating this acknowledgment, but by proceeding at once to the subject with which I have to deal.

That syphilis can be transmitted from parents to offspring few will have the hardihood to deny at the present day. Long after the recognition of the symptoms of inherited syphilis in the infant, however, there would seem to have been a minority of observers who doubted this transmission. Hunter, it is well known, was induced to deny it; but in this College we may fairly claim for the great Scotch surgeon that with him "error was but opinion in the making." During his lifetime and for years after his death his teaching was widely accepted and believed in. Further experience and knowledge, and especially the works of Colles, had shown that much of Hunter's writing on venereal disease was erroneous, and I fancied that, with the refutation of this mistake, the non-belief in the parental transmission of syphilis had been universally abandoned. It was then with surprise that I learnt from Kassowitz that in 1875, more than three centuries after the general acceptation of the fact of hereditary syphilis in the infant, there were still "authorities" who doubted this transmission. As late, indeed, as 1882 Hermann of Vienna published a work in which he endeavoured to prove that the assumption of such a complaint as hereditary syphilis was entirely a fallacy. Considering the recent date of this work, and having regard to the manifest differences between the inherited and acquired complaints, it needs but slight powers of prophesy to foretell that other "authorities" will in the future come forward to support Hermann and their predecessors in Kassowitz's time in the denial as to the identity of the disease in parent and infant. It is easy to predict, moreover, that the grounds of their unbelief as to the hereditary form of syphilis will be based on the theory that the latter is a germ disease, and that what is really transmitted from parent to offspring is not the living germ itself, but merely a toxine or some other product resulting from it. But in the light of our present knowledge doubts as to the transmission to the infant are not within the range of practical controversy, and if there still lingers any smouldering scepticism as to this transmission it is of little import, and I feel I can fairly ignore it without further comment.

I assume then as proven the fact that syphilis can be transmitted from a parent to the infant. I feel I may also take as proven that syphilis in the infant can be derived from the complaint in the father alone or the mother alone, or may be a joint heritage from parents who are both affected. It is true that within comparatively recent times authorities have doubted the power of the father to transmit except through the previous contamination of the mother, and others who have doubted the pregnancy resulting from a tainted ovum proceeding as far as the birth of a living child. Proofs in abundance, however, are forthcoming where, the father alone being infected, the mother has borne a syphilitic infant without presenting the least sign of the complaint herself, and others where a syphilitic mother has produced a tainted infant and the father undoubtedly been free. Any attempt, then, to refute the views of those who have argued otherwise would be superfluous on my part, and I will proceed to attempt an investigation as to whether there are any differences in the frequency and severity with which the infant is affected dependent on the parental source from which the complaint is derived. Apart from the consideration of disturbing elements introduced by such factors as the length of time elapsed from primary infection and the amount of treatment, there are other inherent difficulties in the way of estimating the paternal influence as regards the frequency of transmission of syphilis and its severity in the infant. One such difficulty lies in the fact that the mother may possibly have been affected in the ordinary manner, although she may exhibit no signs of the disease, and then it becomes a matter of impossibility to rightly assign to either parent his or her due share in the production of the complaint. Another difficulty arises from the assumption that every mother bearing a syphilitic infant has herself contracted the complaint from the fœtus in utero—a contingency that will be considered later when dealing with the question of "syphilis by conception." On one point bearing on the paternal influence, however, all observers are agreed. This is that a very large proportion of the mothers of syphilitic infants exhibit no outward evidences of the complaint themselves even after prolonged and careful search. It is only in such cases as these that any estimation as to the paternal influence in syphilitic heredity can be attempted. When writers such as Fournier, who believe in the doctrine of "syphilis by conception," give statistics as to the paternal influence, they simply refer, I take it, to cases where there is certain proof of the disease in the father and where there is an entire absence of the ordinary signs of it in the mother. Fournier's statistics as to the paternal influence, subject to the reservation I have stated, are as follows. From notes of 1127 pregnancies in his private practice where the father alone was manifestly syphilitic he places the mortality amongst infected children at 28 per cent. In his hospital practice, from notes collected by Mademoiselle Krikus, he places the mortality where the father alone was syphilitic at as high a figure as 48 per cent., an increase fully accounted for by the difference of surroundings of the parents in private and hospital practices. Kassowitz, who denies the doctrine of syphilis by conception, gives the following figures: out of 105 pregnancies where the father was syphilitic there were 26 abortions, 21 children who died early, and 58 who survived. This gives a percentage of mortality of 26 5, a result closely in accord with Fournier's record from private cases. I have collected notes from my out-patient practice at Shadwell of 100 families where the mother presented no signs of syphilis and the disease in the infant was presumably derived from the father alone, and a similar number where the mother was unmistakably syphilitic. They are, of course, subject to the disadvantages attaching to notes gathered from patients actually brought for inherited syphilis, and that they refer to infants born at widely differing periods from the times of primary infection. Subject as they are to these sources of vitiation, they are still not without interest. In the first set, where the mother was apparently free from syphilis, there had been 563 pregnancies, resulting in 187 abortions, 193 children who died early, and 183 children still living. This gives the high mortality of 56 6 per cent., but poverty and other factors are probably as much responsible for it as syphilis when dealing with East-end babies. But the mortality amongst affected infants by no means adequately gauges the evils of syphilis on the offspring. Its responsibility for death of the fœtus in utero and the harm wrought by it in infants who survive must also be taken into account in this respect. Fournier, reckoning up the number of abortions and the number of infants attacked by inherited syphilis, and comparing their sum with the total number of pregnancies, has deduced what he terms "indices of harmfulness" (*nocivité*) for parental syphilis. This "index of harmfulness" when the father alone is syphilitic he places at 37 per cent. But a true "index of harmfulness" is only to be arrived at by following out the whole of the child-begetting histories of numerous syphilitics; an opportunity, however, for doing this is never likely to fall to any one observer. Were it possible to gain such statistics I cannot but think that Fournier's "indices of harmfulness" would be materially lowered.

The marked effect of time in decreasing and annulling the power of the father to transmit cannot be gainsaid. But it is difficult or rather impossible to give any definite limit of time beyond which this power of transmission is entirely lost. Mr. Hutchinson is probably right in the main in limiting the time during which the father can infect the mother at five years from the date of his own infection and also in his statement that such an eventuality is rare even after the

Digitized by Google

lapse of only three years. That the power of infecting the offspring, however, may long outlast that of directly infecting the mother cannot be doubted. Kassowitz from his own experience would give the limit of time during which transmission to the offspring is possible at from ten to fourteen years after primary infection, and he also propounds the important aphorism that if there is even a remote chance of the mother being contaminated in such a case inheritance by her offspring is a certainty. That the power of transmission can be retained by the father for a longer period than that assigned by Kassowitz is sufficiently proven. Henoch quotes a case from his own experience where syphilis in the infant was due to disease contracted by the parent more than twenty years before. Dr. George Ogilvie has published a case in which amongst other interesting facts was the one that nineteen pregnancies, spread over nineteen years from the date of infection of the father, all resulted in syphilitic infants or abortions, and this in spite of prolonged and vigorous treatment. Dr. Colcott Fox mentioned at a meeting of the Royal Medical and Chirurgical Society that he had known a case where the transmission from parent to infant took place more than twenty years after primary infection. Dr. Eustace Smith, too, tells me of the following case. A man married fifteen years after contracting syphilis; his wife during the first five years of her married life had several abortions. Dr. Smith saw the first living child, born more than twenty years after the contraction of the disease by the father, and it was deeply syphilitic although the mother was apparently a strictly healthy woman. I have personally known a case where the fourteenth pregnancy, sixteen years after the incurrence of syphilis, resulted in a tainted infant. Happily, such cases of long retention of the power of transmission are rare. In very exceptional instances, however, it might well be, judging from the cases given, that the power of transmission is only limited by the child-bearing or child-begetting capacities on the part of the parents.

That time alone, independently of any treatment, may abolish the capability of the father to transmit is undeniable. Before finally annulling the power of transmission lapse of time engenders the quality of rendering transmission less certain. When this stage is reached at which transmission is uncertain though possible it becomes a mere matter for surmise what determines the infection of the infant in one case and freedom from it in another. That such infection is dependent upon any fresh outbreak of symptoms in the father is not proven. All the same, I should consider the father more likely to transmit the disease at a time when he had outward manifestations of the complaint than he would at a time when all symptoms are latent. At whatever period of the disease the father transmits, if he transmits at all, he probably does so with the same intensity as he would do at the beginning of his syphilis when transmission was almost certain. The case of an infant in this respect is identical with that of a woman. When a man late in his syphilis, having reached the stage at which transmission is uncertain, contaminates a woman, there is no proof that such a woman acquires a milder form of the disease than she would have acquired at a time when his syphilis was recent and transference certain. In other words, there is no proof that lapse of time brings with it attenuation of the virus. And so with regard to the infant. When a syphilitic man and a healthy woman bear a succession of infants I grant the gradual lessening of the severity of, and tendency to eradication of, the complaint in each succeeding infant. This diminution of the symptoms in successive infants by the same couple, where the father alone is syphilitic, is not, however, necessarily dependent on the assumption of any progressive increase of attenuation of the virus in the man. In fact, I believe that such lessening severity in the successive infants is independent of the father and due entirely to the presence of some product in the mother, this product being by her absorbed from the fœtus *in utero* and in amount proportional to the number of syphilitic conceptions she has carried. When a syphilitic man, by the same woman, has begotten a succession of infants in the latest of whom the syphilis has decreased to the vanishing point, we have no proof that, if he still retain the power of transmission, he would not in other women beget infants with syphilis as virulent as that in the initial conception by the first woman. Indeed, such slight evidence as we possess would tend to prove that he would. Plenty of cases are on record where men, many years after infection, have begotten infants with syphilis as virulent as in any born within a short period after the primary disease. Diday's law of decreases I hold to be true in the main, but only as regards infants from the same couple.

The effects of treatment in limiting the power of transmission are still more marked than those of time alone. But again we have no proofs where the man alone is affected that treatment any more than time can furnish an attenuated virus, and, however fully a man may have been treated, if he transmit at all he probably transmits in full to woman or infant. Obviously such a rule does not apply in the case of the woman, for the mercury taken by her may help to mitigate the disease of the fœtus *in utero*. What would seem remarkable about mercury is not its power of attenuating the virus transmitted, but its power of temporarily preventing transmission altogether, and especially if it be administered about the times of procreation. A case recorded by Fournier is a striking example of this: "A young man, against the advice of the last-named, married in the first year of his syphilis, but continued his treatment. His wife conceived and bore him a healthy infant. Thinking by this latter fact that he was absolutely cured he left off his mercury; he then infected his wife, whose second pregnancy resulted in a deeply infected infant." Diday, too, quotes cases where by the administration or withholding of mercury healthy or infected infants were alternately produced. There is, however, a mathematical precision about some of these cases that makes them difficult of acceptation. All the writers, however, in dealing with this power of mercury describe the infants born under the conditions in question as "healthy" and not as merely suffering from a mitigated form of the disease.

Time and treatment are concerned in another question of great practical importance—viz., the date at which marriage should be sanctioned in a man after the incurrence of syphilis. A definite answer, applicable to all cases, is, I think, impossible and unadvisable. The age at which the disease was contracted, the varying degrees of severity of the symptoms, the amount of treatment and the lapse of time over which it has been spread, are all factors which must largely qualify the answer in every instance. As it may be of interest I will give the dates after primary infection at which some modern authorities consider a man is justified in marrying with a fair prospect of not transmitting the complaint to wife or offspring. Schuster of Aix-la-Chapelle, who has written a *brochure* on the subject, places the date at two years after primary infection. Mr. Hutchinson finds the same period, and says he has only once had to regret his sanction to marriage after this interval. This is, perhaps, more a tribute to the results of his treatment than a warrant of justification for others to follow his example in sanctioning marriage at so early a date. Mr. Hutchinson, however, is emphatic on the point. "Probably," he writes, "in the vast majority of cases the risk of transmission to children is over long before the end of two years." With this favourable view of the matter I cannot but think he will find many authorities to disagree. Mr. Cooper would allow marriage three years and Fournier and Otis four years after first infection. Kopp and Lesser would extend the time to as long as five years. Personally I am in most cases in favour of the longer interval. The responsibility of sanctioning a marriage with any risk of imparting syphilis to others is not to be lightly undertaken. Diday's sarcasm "that the extreme caution displayed by some authorities on the matter would soon depopulate the earth" I think can be ignored. If treatment has been thorough and delay of marriage in any way detrimental I would shorten the interval to one of two years after the disappearance of all active symptoms, or to one of three years after primary infection. In no case would I sanction marriage until at least three months after the disappearance of active symptoms, no matter how long a time had elapsed between their appearance and the incurrence of the complaint.

That syphilis in the mother can be transmitted to her infant when the father is healthy is now placed beyond all manner of cavil or doubt. It was the mother alone that Hunter accredited with the transmission of the complaint in the days whilst he yet believed in the reality of hereditary syphilis. As the father is the introducer of syphilis into the household in the vast majority of instances, it is somewhat difficult to meet cases of hereditary syphilis where there is a positive guarantee of the mother's sole responsibility for the transmission, and on this point I have to rely on the

Digitized by Google

statistics of others. Fournier has recorded the cases of 13 syphilitic women whose husbands were free, and 28 pregnancies in these women resulted as follows: 7 children living, 4 syphilitic; 15 infants died at birth or soon after; and 6 abortions. Fournier gives the percentage mortality amongst infants born alive of syphilitic mothers as 60, but it reaches as high as 68 1 if calculated from the figures last given. Kassowitz records the results from his own practice of 40 pregnancies where the mother alone was syphilitic and they gave 18 abortions, 5 children died early, and 17 living children. This gives a percentage mortality of only 22 7 as compared with Fournier's 60, but the percentage of abortions is incomparably higher in Kassowitz's figures than in Fournier's. Elsewhere, too, Kassowitz gives the mortality amongst syphilitic infants inheriting from the mother alone as 80 per cent. Fournier's index of harmfulness for maternal syphilis is 84 per cent.; but as he probably formed it on statistics drawn from mothers bearing infected infants, it is in all likelihood much too high if intended as applying to the whole community of infected mothers. Two other questions concerned with syphilis in the mother—the effect on her offspring of her contamination during pregnancy and "syphilis by conception"—I purpose dealing with later.

In attempting to estimate the influence of syphilis in both father and mother upon the offspring the disturbing elements of time and treatment have redoubled force, as here they have to be reckoned with in each parent instead of one only. Fournier, from statistics gathered under conditions as identical as the case permits of, places the mortality of infants where both parents are syphilitic at 68 per cent., as against 28 where the father alone and 60 where the mother alone is syphilitic. Kassowitz, out of 76 pregnancies where both parents were affected, found 28 abortions, 24 infants that died early, and 24 infants that survived, this giving a mortality of 50 per cent. The same author, however, in another series found the mortality as high as 69 per cent. From my notes of 100 families where the mother was syphilitic, and in the vast majority the father syphilitic also, I gather the following statistics. In these 100 families 539 pregnancies resulted in 189 abortions, 203 infants who died early, and 147 living children. This gives a mortality of exactly 58 per cent., a result not differing greatly from that obtaining in my cases where the father alone was affected. Fournier's index of harmfulness rises to 92 for the mixed type of inheritance. Statistics such as I have given as to the parental influences in transmission are subject to many faults and discrepancies. For a due and reliable estimation of these influences and their effect upon the progeny we want more detailed statistics than have as yet been furnished us. Thus, it would be of value if we had the results of pregnancies tabulated according to the number of years elapsing from the dates of primary infection. As an example of this Kassowitz gives the figures for 90 pregnancies of women contaminated by their husbands and conceiving in the first year of their syphilis and these resulted in 50 abortions, 38 infants who died early, and only 2 infants who survived. Further statistics of a like character and others giving details as to successive pregnancies independently of the times elapsed from infection might be of great practical utility and interest. Rough and imperfect as the statistics are that I have given, I think that they indubitably show that maternal syphilis is more deleterious as regards the offspring than a paternal one, and that the mixed type is the most serious of the three. The extra severity of the one type over the other, however, is, I believe, entirely exercised upon the fœtus *in utero* and has no influence after birth. The greater severity upon the fœtus of a maternal syphilis over a paternal one is due, probably, to the reason unusally assigned for it, the deleterious influence of the vitiated maternal fluids upon the fœtus *in utero*; and the slight increase in the mixed parental type over the maternal one is possibly owing to a greater certainty and frequency of transmission. Mr. Hutchinson writes: "There is no reason for believing that the infection from the mother (germ transmission) produces more serious results than sperm transmission or that the child who inherits from both parents suffers more severely than he would if one were free." Exceptions to this rule, he admits, occur in cases "in which children are born with syphilitic lesions actually present or with traces of intra-uterine disease." If I interpret these sentences correctly Mr. Hutchinson would seem to agree with me as to the extra severity of one form of inheritance over another being entirely exercised during intra-uterine existence. As a practical point, in any infant brought at the usual age for treatment I know of no facts that would justify any qualification of prognosis depending on the parental source from which its syphilis might be derived.

I turn now to a subject of practical importance and interest, the effect upon the fœtus of a syphilis contracted by a mother during her pregnancy. For many years one set of authorities strongly asserted that in this contingency the fœtus was usually infected and another set as strenuously denied it. Even at the present day, in fact, it cannot be claimed that the dispute is settled to the satisfaction of all, although the possibility of infection of the fœtus is commonly accepted. Diday, who is much quoted on the point, lays down the curious rule, and defends it on the anatomical relations of the placenta, that if a mother is infected during the first forty days or after the seventh month of her pregnancy the child will escape, but the latter will be syphilitic if the mother be infected in the interval between these times. Kassowitz justly asks, however, if a mother infected during the first forty days of her pregnancy is not syphilitic also in the interval during which Diday claims transmission is probable? Ricord writes: "If the infection of the mother takes place during the last three months it is not certain that transmission is possible." Mr. Hutchinson, again, doubts whether a woman would be likely to go to the end of her pregnancy who had suffered from constitutional syphilis in the early part of it. Most of the facts in his own personal knowledge occurred in cases in which the disease was incurred by the mother late in pregnancy. There is then great discrepancy amongst authorities as to the time during pregnancy when infection of the mother can occur with the production of a syphilitic infant. Fournier, who believes in the infection of the infant through a syphilis incurred by the mother during pregnancy, follows Cazenave and Diday in adopting the name of "congenital syphilis" for the type of complaint in the infant under these conditions, restricting that of "inherited syphilis" for the class of cases originating at times of conception. He, moreover, claims that the symptoms of this "congenital syphilis" are easily distinguishable from those of inherited syphilis. Mr. Hutchinson will not admit of any possible differentiation of symptoms in the two classes and throws the onus of proving any difference between them on those who assert it. There is then as great a contention amongst leading authorities as to the symptoms in the infant as there is regarding the times of pregnancy at which a mother can be infected with transmission to the infant. Kassowitz and other German authorities deny the transmission to the infant at whatever period of pregnancy a mother may be infected. There is no proof, Kassowitz argues, that in any one of the cases where a mother was infected during pregnancy and produced a syphilitic infant that such syphilis was not derived from the father at the time of conception. But if he admitted the possibility of the carrying of a syphilitic fœtus for several months in her uterus, and the subsequent contamination of the mother, Kassowitz in this way allowed the possibility of what is in reality an equivalent of a breach of the first part of Colles' law, a deduction from his belief that would seem to have escaped this astute observer. Personally, I have no experience in the matter; but in all the cases of this nature under the care of my friends the infants escaped. I have, moreover, met with twins born of a syphilitic mother where the one infant was deeply affected and the other apparently free, and I know of similar cases under my colleagues. This circumstance would seem to show that there is no imperative necessity for the inoculation of the fœtus by a syphilitic mother's blood, and also that infection of the fœtus is probably most often effected through the ovum. Henoch has never known a case of a mother contaminated during her pregnancy, but he deems transmission to the infant likely under such conditions. Birch Hirschfeld knew three instances where a mother was infected during pregnancy. The infants born from these pregnancies died soon after birth from some complaint other than syphilis, and the necropsies revealed no trace of the last disease, not even the characteristic changes so generally found in the epiphyseal cartilages. Birch Hirschfeld, nevertheless, believes that transmission is possible to the infant under the conditions in question, but that such transmission is not possible so long as the integrity of the endothelial barrier between the maternal and fœtal circulations is maintained. He claims to have proved that any affection of this endothelial barrier permitting of the passage of micro-organisms from the mother to the fœtus is secondary to serious vascular disease

Digitized by Google

in the maternal portion of the placenta. If his views are correct, then contamination of the fœtus under the conditions in question must be allowed as possible, but abortion or the entire escape of the fœtus would seem much the more probable event. When writers like Mr. Hutchinson and Fournier cite cases where the infant has inherited the disease incurred by its mother during her pregnancy, I take for granted that they have satisfied themselves as to the freedom of the father at the times of conception, and I accept the possibility of the transmission to the infant. Nevertheless, I believe that what is possible has unwittingly been exalted into what is probable. To thoroughly settle several of the points concerned in the question we want the publication of further cases giving details as to the freedom of the father at the time of conception, the date of infection of the mother in her pregnancy, and a full description of the symptoms in the child.

The converse of the preceding question, the effect upon the mother of the blood returned to her through the placenta from a syphilitic fœtus, may appropriately be taken here. This, amongst others, involves the much debated subject of "syphilis by conception." First prominently promulgated by Ricord and Diday, the doctrine of "syphilis by conception" has been alternately advanced and denied by every eminent writer on syphilis since their time. Some of the uncertainty and contention on the subject has undoubtedly arisen from a want of due appreciation of what is really implied by "syphilis by conception." It is not very uncommon to find the term used in connexion with the disease in the infant—a strange confusion of ideas. Under these circumstances I trust it will not be deemed superfluous if I define what is implied by the term. "Syphilis by conception" is the syphilis supposed to be acquired by a healthy mother by means of the tainted blood, returned to her through the placenta, from a syphilitic fœtus infected by the sperm of the father—a "syphilis by return shock," as Diday calls it. The term, of course, implies an escape of direct infection of the mother by the father, and that her syphilis is solely and entirely due to the fact of her conceiving. It is claimed by many eminent authorities that if a woman cohabit with a man incapable of directly contaminating her, but who is still capable of transmitting to the fœtus, such cohabitation may be harmless to the woman unless she conceives, but that this last condition of necessity leads to her impregnation with syphilis. More than this, the syphilis, such writers allege, which had lost much of its virulence in the man is merely from the fact of conception on the part of the woman regenerated in her with all its initial virulence—"*vires acquirit eundo*," as Diday quotes. Such are some of the principles underlying the theory of "syphilis by conception." It is a syphilis, its upholders claim, agreeing with one acquired in the ordinary way in all secondary manifestations and sequelæ, but nevertheless possessing certain characteristics peculiar to itself. Fournier, the most able advocate of the doctrine at the present day, has styled it a "syphilis decapitée," inasmuch as with it there is an entire absence of primary chancre and enlargement of the corresponding glands and the periods of primary and secondary incubations are abolished. For the establishment of "syphilis by conception" in any particular instance its upholders allow that proofs of the following essentials must be forthcoming: (1) That the father was free from any innoculable lesion at a time when the date of the mother's syphilis was consistent with direct acquirement from him; and (2) that the mother has always been free from any primary chancre and any enlargement of glands resulting from the presence of one. The first requisite for the establishment of "syphilis by conception," the absence of innoculable lesion in the father, is absolutely incapable of proof in any instance. It is impossible for any one of us to guarantee the freedom of any patient in this respect at all times and seasons. In many of the published cases, too, of syphilis by conception it is recorded that sores on the scalp, palmar psoriasis, and such like trifles were missed; and, this being so, how much more readily might a slight abrasion of the penis be passed over by a layman? Such a lesion might, moreover, be easily missed by a medical man even with ample opportunities of examining his patient. The history, then, of the freedom of the father from innoculable lesion is in no case a partial proof of the possibility of syphilis by conception.

The second requisite—the establishment of the absence of a primary chancre and enlargement of the corresponding glands in the mother—stands on an equally unsatisfactory basis as the preceding one. In a large number of syphilitic women who have never been pregnant the site of the primary lesion is impossible to locate. There are admitted difficulties in this respect applying to women that do not obtain in men. But even in men a careful observer like Mr. Hutchinson has to admit that "in not a few cases he has been unable to ascertain the original site of innoculation." The absence of proof, too, of any glandular enlargement is not conclusive of its non-existence or of that of a primary sore. When the latter is high in the vagina or on the cervix uteri the demonstration of enlargement of the corresponding glands may be physically impossible. How, then, can it ever be proven that the syphilis of a pregnant woman is acquired through the agency of conception when there are such insuperable difficulties in establishing her non-acquisition by the ordinary channels?

If we turn to the descriptions furnished by the upholders of the doctrine we find a marked discrepancy amongst them as regards the times of onset of the complaint after conception. Fournier would seemingly place the time at as early a date as three weeks after this latter. He gives the case of a young woman who developed syphilis soon after marriage and in whom he could find no primary chancre or trace of inoculable lesion in her husband. At the woman's monthly period, however, shortly preceding her syphilis the menstrual flow was attended with more pain and some firmer clotting than usual. Fournier gravely argues from this that, as there was no proof of primary contagion, this undue clotting and pain were owing to the expulsion of a three weeks' fœtus, and that the short sojourn of this last *in utero* was sufficient to account for a syphilis by conception in the mother. Most of us would, I fancy, however, find a less subtle explanation of such a syphilis. If Fournier is correct in his interpretation, and syphilis by conception can manifest itself after so short a period as three weeks after impregnation, then in other cases the pregnancy should never be far advanced before the appearance of symptoms. Diday, however, who is chiefly responsible for the doctrine of "syphilis by conception," suggests parturition, or shortly after, as the time at which symptoms of such a syphilis are most likely to appear. There is, then, seemingly a most marked disagreement amongst the upholders of the doctrine on one of its most vital points. Diday is, however, quite clear in his teaching as to the frequency of such a syphilis. "If a woman bear a syphilitic infant," he writes, "I say she has had the complaint herself." Fournier is equally emphatic. According to him, pregnancy with a tainted fœtus, however short a time it may last, implies the certain acquisition by a woman of "syphilis by conception." If there are none of the outward signs of syphilis in such a woman, then, according to Fournier, she has it in a latent form. As a proof of the reality of this last condition cases have been instanced where women have borne infected infants by syphilitic husbands, and although presenting no early symptoms of the disease themselves have in later years appeared with tertiary ones. That such cases do occur will be readily granted, but they are not restricted in occurrence to fertile women. Cases of sterile women, and of men also, in whom the presence of tertiary symptoms is accompanied by an absolutely negative history as regarded primary and secondary manifestations are far from rare. Charrier's case of this nature, quoted by Fournier, Messrs. Cooper and Cotterell, and others, is to me an ordinary one of a woman in whom, owing to the mildness of the secondary symptoms, the complaint had been missed until the supervention of gummata. Such cases, were they infinitely more common than they are, go but a slight way to prove the reality of "syphilis by conception," latent or manifest.

The preceding are not all the arguments that can be adduced against the theory of "syphilis by conception." Diday, as I have already stated, is generally credited with being the founder of the doctrine. Most of those, however, who have accepted his teaching on the point would seem to pass unnoticed the deductions he drew from it. This is what he terms the "law of increases," and it would seem to me a fairly logical outcome from the establishment of this "syphilis by conception." By this law, Diday asserts, every conception on the part of a woman by a syphilitic partner adds to her syphilis, and these additions tell in their turn upon the fœtus, and thus each succeeding pregnancy results in a product more syphilitic than the preceding one. The "law of decreases," the lessening severity upon the fœtus in each successive pregnancy, only applies, he asserts, to cases where the mother or both parents are affected. When

Digitized by Google

the father alone is affected, which applies to by far the greatest number of cases of inherited syphilis, this "law of increases" condemns each successive infant in a family as more syphilitic than the last—a dreadful state of things to contemplate if true. But fortunately, I think, all experience proves its falsity and that of the theory that gave it birth. It is repulsive enough that a woman should be compelled to bear syphilitic infants against her will. This repulsiveness would be vastly increased if "syphilis by conception" were proven and that such a woman could be tainted from her unborn infant. The one slight tittle of evidence in favour of the possibility of "syphilis by conception" is that afforded by Ricord and Diday, and Henoch quotes Fournier and Mr. Hutchinson to the same effect, that they have known women to have lived long with syphilitic partners and escaped contamination as long as they remained sterile, but conception brought syphilis in its train. But cases such as these, where proof of infection by the ordinary methods is wanting, are not sufficient in number to free them from the class dependent on mere coincidence.

I have stated my disbelief in the theory of "syphilis by conception" and have given the reasons for that disbelief. The theory no doubt arose from the immunity to syphilis displayed by mothers bearing affected infants. That such mothers do enjoy immunity, partial or complete, would seem almost universally accepted at the present day. But immunity to syphilis by no means entails the necessity of having passed through an attack of the disease itself. In accordance with all modern teaching there is every justification for the supposition that syphilis is a disease dependent upon a specific micro-organism. It is true that hitherto attempts at identification and cultivation of the responsible organism have not met with a success universally acknowledged. Notwithstanding the failures, or perhaps partial successes, of Lustgarten, Klebs, and others, the prevalent opinion that syphilis is a germ disease has not been shaken. If, then, syphilis be a germ disease, the termination of an attack in the individual is brought about by the evolution by the germs themselves of some chemical principle antagonistic to their own growth and existence. By analogy with other complaints this chemical product is possibly an antitoxin, the syphilitic equivalent of that occurring in diphtheria. Now, if the syphilis in an infant, inherited from the father, is ever a contagious disease, this last of necessity implies the transference of active micro-organisms from the father to the fœtus. Once implanted in the fœtus, the evolution of these micro-organisms could be active ensue a as in extra-uterine life, and with their growth would *in utero* corresponding production of the "syphilitic antitoxin." Now the possibility of the passage of such a substance as this "antitoxin" into the maternal circulation no one would contest, although many would do that of the germs themselves, with the consequent syphilisation of the mother. Chauveau has recorded some observations with a close bearing on this point. He claims to have proved that when gravid sheep are inoculated with "symptomatic anthrax" the lambs they drop are immune to that complaint. This immunity, too, Chauveau states, is not due to the direct passage of the anthrax germs themselves to the lambs, but to that of some product generated in the mother and absorbed by her progeny by means of the placental vessels. In an exactly analogous manner to this last, although the direction of the stream is reversed, I would suggest that a mother may absorb the antitoxin from her syphilitic fœtus and so gain immunity for herself, partial or complete. In this way such a mother, without having incurred the actual complaint herself, may have gained the position of one who has passed through and recovered from an attack of syphilis. In this last deduction from the germ theory of syphilis I am seemingly supported by many. For a further deduction—a wild speculation it may be called—I fear I must charge myself with the sole responsibility. It has occurred to me that if the immunity in the mother has been gained by the absorption of some "antitoxin" from the fœtus, this substance may in its turn beneficially react upon the fœtus *in utero*. In the case of a first conception the absorption of the "antitoxin" by the mother, and its consequent diffusion through the two circulations, may be detrimental to the fœtus and to some extent explanatory of the more untoward results of first syphilitic pregnancies. But in succeeding pregnancies the mother's "antitoxin" would act upon the fœtus from the start and with much more marked effect. With each pregnancy the amount of antitoxin in the mother would be increased, and it may be that its accumulation would be sufficient to cure the disease in later conceptions, although all the time the father transmit in full. Such a theory would seem to me fairly explanatory of the extra severity of the complaint in the first infant in a family, the lessening severity in each successive infant, and the final disappearance of the complaint in the latest ones. It would also account for the greater severity *in utero* of a mixed parental or maternal syphilis over a paternal one. By the theory, too, the later infants in a syphilitic family, although presenting no signs of the complaint, should be immune to it, and possibly also the earlier infants by a second husband, who is free, of a woman who has borne infected infants by a former partner. In conclusion, I would suggest that if the serum treatment of syphilis is deemed worthy of further trial such serum should be taken from mothers who have borne affected infants and themselves remained free, rather than from persons broken down with tertiary symptoms.

The Lumleian Lectures

ON

THE SEQUELS OF DISEASES.

Delivered before the Royal College of Physicians of London

BY SIR DYCE DUCKWORTH, M.D., LL.D. EDIN.,

FELLOW AND TREASURER OF THE COLLEGE; PHYSICIAN AND LECTURER ON MEDICINE, ST. BARTHOLOMEW'S HOSPITAL; AND HONORARY PHYSICIAN TO H.R.H. THE PRINCE OF WALES.

LECTURE III.[1]

Delivered on March 26th.

MR. PRESIDENT AND GENTLEMEN.—The sequels of *Syphilis* are now amongst the best recognised disorders we have to deal with. Their variety, complexity, and far-reaching nature are well appreciated. Much light has been thrown upon them in the course of the last thirty years, and many labourers have worked in this field of pathology, not a few of whom have been our own countrymen. We may feel sure that a great variety of disorders depending on manifestations of syphilitic virus constituted difficult problems for solution to our predecessors, and, no less, enabled many of them to score remarkable successes in the days when mercurial treatment was so largely, and in an empirical routine fashion, in vogue. For the most part, it may be affirmed that the sequels of syphilis pertain to adult and middle life. I am reminded here of an axiomatic declaration of the older physicians related to me by our learned librarian Dr. Munk, to the effect that many of the mysterious and puzzling cases of disease occurring in early life generally depend upon tuberculous processes; those commonest in middle life upon syphilis; while those occuring in later periods are generally dependent upon gouty manifestations. In these days we do well to recall the wisdom and shrewdness of the great men who have preceded us, for we are rather apt to think that we have lighted our own torches, and to regard those handed on to us as but feeble and flickering links. Our modern electric illumination sometimes fails us, and we may be glad to fall back upon the older sources of light. We have to note as sequels some of the so-called secondary phases of syphilis, and may not only regard in this light such symptoms as appear after a period of apparent complete restoration to health in the form of late, or so-called tertiary, manifestations. These appear from one to two years after primary contagion and may recur any time within the life of the patient. Yet we can draw no hard and fast line between the end of the period in which secondary and that in which tertiary troubles may arise. Attention has recently been directed to the onset of grave nervous symptoms, such as paraplegia from transverse dorsal myelitis, general analgesia, anæsthesia, and acute multiple neuritis in patients at an early period after primary infection, at a time, that is, when secondary manifestations are most likely to occur. So, too, neuritis, affecting single nerves,

[1] Lectures I. and II. were delivered on March 19th and 24th respectively, and were published in THE LANCET of March 28th and April 4th.

Digitized by Google

may be an early occurrence. Syphilis, as a destroyer of arteries, may act in this fashion, with the production of grave symptoms within the first year of primary infection, at a period when only secondary manifestations are to be expected. Dr. Sharkey has recorded a case in which death occurred from disease of the cerebral arteries in the seventh month of syphilis while a secondary eruption was still present on the body. The late Dr. Bristowe recorded a like case in which death occurred from obstructive endarteritis, cerebral softening, and meningitis six months after the occurrence of the primary chancre, while secondary scaly syphilides were still present on the skin. The importance of a due recognition of these facts is great in respect of prompt and adequate treatment, since early lesions of this character are distinctly more amenable to the influence of mercury than are those which arise in the later or tertiary stage, and they are prone to begin slowly and to prove both chronic and rebellious under any treatment. These early sequels pertaining to the secondary or constitutionally active period of the disease are apt to develop rapidly, with serious disturbance of the general health. They are often productive of symmetrical lesions, and they quickly subside on appropriate treatment. We may not look for them, as Mr. Hutchinson tells us, within six months of the date of the primary lesion. Most of them relate to the arteries of the pia mater of the brain and spinal cord and in this way lead to nervous symptoms. The nervous elements may, however, be primarily involved in this stage, as evidenced by the occurrence of neuritis and myelitis with both motor and sensory symptoms. In this secondary stage the blood and inflammatory secretions of the patient are infective and capable of originating a chancre. The later or tertiary sequels occur without constitutional disturbance, slowly, generally unsymmetrically, and are more distinctly local in character. The patient's blood and secretions are non-infective in this stage.[2] Mr. Hutchinson is disposed to regard all tertiary symptoms of syphilis as true sequels, or more strictly "regroaths." In support of this view he and other authorities adduce evidence showing that persons have become the fathers of families of healthy children, and have subsequently developed tertiary lesions. In such cases there must have been freedom from constitutional taint, although local conditions remained in a condition of latency or abeyance ready to be evoked by some determining excitant. It would be unseemly and unnecessary in these lectures to present to my audience any detailed account of the manifold tertiary symptoms of syphilis regarded as sequels, such being now matters of common knowledge. We are happily aware of the fact that in the majority of cases of primary syphilis prompt, adequate, and sustained treatment suffices practically to cure the disease and to avert the onset of sequels throughout life, and so we may fairly regard their occurrence as evidence either of imperfect original diagnosis or of incomplete treatment. The pathogenic conception of the malady as one dependent on a specific micro-organism helps us in forming an opinion, judging by analogy with the behaviour of other like organisms, that such particulate agents may long lie dormant in certain tissues and only wake up into activity under various provocations, such as irritation, exposure to exhausting agencies, depressed vitality from the inroad of other diseases, and traumatism. The unsymmetrical character of these consequent lesions affords some evidence of their local and non-constitutional nature. I have already referred to the occurrence of tabes dorsalis as a definite sequel in most instances of antecedent syphilitic infection, and I may add, too, that of general paralysis of the insane as one standing often in the same category. In my first lecture I adduced the fact that when women presented the symptoms of locomotor ataxia they were commonly found to have been at one time the subjects of constitutional syphilis. I regarded this fact as affording strong evidence of the former disorder being in consequential relation to the latter, as, in short, a quaternary sequel of syphilis. This contention is, I consider still further supported by the occurrence of examples of tabes dorsalis in both husband and wife. My colleague, Dr. Ormerod, has reported two examples illustrating this condition and he has referred me to a series of four or five other pairs of cases which have been recorded in this country, on the continent, and in Canada, also to cases of pairs of general paralysis of the insane, nearly all of which distinctly prove that syphilis was the common antecedent factor. I therefore regard this evidence as irresistible and practically proving the case.[3] In some of these instances the husband had tabes, and the wife general paralysis, or *vice versâ*. Even tabes dorsalis has its own intercurrent sequels, amongst them being the peculiar acute onset of a riotous arthritis known as Charcot's arthropathy, which may affect several joints; also perforating ulcer of the foot, and the several varieties of crises, whether gastric, laryngeal, rectal, or vesical. We may note several degrees of gravity in the cachexia of inherited syphilis. There are often to be noted indications of a merely slight taint, such as anæmia, earthy complexion, and perhaps one or two characteristically modified teeth. General growth may be but little interfered with. In the graver cases we have usually present many, if not all, of the specific physiognomical indications, and in viable cases full development of the body is never reached. It is important to recognise even the minor indications of such taint, inasmuch as they may serve to throw light upon subsequently occurring obscure symptoms, and so afford a guide to treatment. Twelve years ago Mr. Hutchinson expressed the opinion that it is not the diathesis of syphilis that is transmitted from parent to offspring, but the germs of the disease itself—the particulate elements of the virus[4]; a transference, therefore, of contagion rather than hereditary transmission. "A child inherits syphilis in precisely the same sense and in precisely the same manner as it may inherit small-pox." He believes that "no minimised transmission of syphilis is possible." The child gets either nothing at all or the germs of the disease, and in the latter case they will, subject to the laws of idiosyncracy, develop equally in all cases. The minor indications of this specific taint I have alluded to may be amongst those which have not been permitted to develop fully owing to some inhibitory condition. Paralytic dementia, ophthalmoplegia, a variety of epilepsy, grave arterial atheroma, and general arterial sclerosis are certainly due sometimes to pre-existing syphilitic taint. These conditions have been called by Fournier parasyphilitic affections, by some post-tertiary, or quaternary. Lardaceous degeneration may sometimes be clearly traced to previous syphilis, not merely as an associated condition with gummata and a resulting fibrosis as in ordinary tertiary sequels, but as an independent and widely-spread degeneration both of viscera and of other portions of the frame, constituting, indeed, a variety of so-called syphilitic cachexia. Congenital syphilis may sometimes be followed by manifestations of Raynaud's disease with gangrene of fingers and toes. I have seen several examples. The conception in regard to these conditions is that the remote lesions are not directly due to syphilitic toxine, or to growths determined by it, but that a constitution having been once tainted by this special virus and its ravages, becomes a prey to other specific degenerative changes which would in all probability not have occurred in persons not subjected to such an ordeal. With several authorities I am in accord in regarding the occurrence of aneurysm as, not infrequently, a sequel of syphilis, and this contention is strengthened by the fact that when this condition occurs in women, which is rare, they have commonly been the victims of syphilis. The same view is also tenable, in my opinion, in respect of cardiac aneurysm, which is usually a result of gummatous carditis. The latest researches on syphilis support the view of Paget and others, that the long-delayed manifestations of syphilis plainly indicate that there remain in the tissues of the body residues of the disease after apparent recovery, and that these may be roused into activity, affording specific characters of their own or modifying the signs of other morbid conditions with which they may be associated or combined, such as gout and struma. Examples of this latency pertain, indeed, to each phase of syphilis. Thus, there may be remarkable delay in the formation of a hard chancre after primary infection. An indolent bubo has been known to precede the occurrence of induration on the penis by seven weeks, according to Mr. J. Hutchinson, jun. Secondary symptoms followed in due course with a more active condition of the bubo. A period of ten weeks was noted by Aimé Martin in another case before the occurrence of a hard chancre.[5] Delay in the

[2] For many of these statements I am indebted to Mr. Hutchinson's address at the Royal Medical and Chirurgical Society introductory to a discussion on Affections of the Nervous System occurring in the early (secondary) stage of Syphilis. 1895.

onset of secondary symptoms has also been carefully noted. M. Diday's observations show, and Mr. Hutchinson confirms them, that intercurrent illnesses may cause such postponement. Thus, typhoid fever and pneumonia have been proved to cause postponement of secondary symptoms for periods varying from three to over five months, the activity of the specific virus being suspended till recovery from these illnesses had taken place. These facts are very remarkable. Mr. Hutchinson, jun., has recorded an example of extraordinary prolonged latency in respect of tertiary manifestations. A man contracted syphilis at the age of twenty-one years, had secondary symptoms, and remained wholly free from any lesions till, after exposure to much privation, he had, at the age of fifty-three years, multiple nodes on the skull, ischium, and humerus. For thirty-two years, therefore, there had remained potential elements within the body ready to resume activity on due provocation. The only analogous condition to this is that presented by the strange behaviour of the malarial organism which has a similar propensity to lie long dormant or latent within the body. "It is seldom that a syphilitic process develops thirty years after the malady, whether it be a direct or indirect process. ..... A period of thirty years after the primary disease brings most patients into the degenerative period of life ..... but the syphilitic virus has then generally ceased to act."[6] It is highly probable, but not yet proved, that the infective microbes, if such they be, or possibly their germs, are present in tertiary deposits and completely localised there, though not always inactive. Some arguments in favour of this view have lately been adduced by my former house physician, Dr. Parkes Weber, in two able papers on the subject of Syphilis published in the *American Journal of the Medical Sciences*. He further expresses his belief that in the post-tertiary or quaternary sequels, such as tabes dorsalis, microbes will not be found, and that thus there is a clear demarkation between tertiary and quaternary lesions. He is also of opinion that the metabolic products of the specific organisms have, like those of the staphylococcus pyogenes aureus and the bacillus pyocyaneus, the peculiar property of inducing lardaceous formation in their immediate neighbourhood.[7] The presumed localisation and latency, or comparative latency, of surviving microbic germs appear adequate to explain the fact that persons so infected may long continue to produce healthy children, for our latest conceptions of syphilis lead us to regard the various active processes which it induces as the results of the presence of developed organisms circulating abundantly in the blood in the secondary exanthematous stage, and leaving behind germs localised in various textures which are inoperative till some exciting cause sets up their development with new tissue-growths and other tertiary manifestations in later stages.

Pyæmia.—There are sometimes to be met with cases of chronic arthritis or of articular deformities, with ankylosis, which have developed from an attack of pyæmic arthritis, which may have occurred perhaps many years previously. Malignant endocarditis is sometimes a sequel of pyæmia.

Having now described the various sequels which are recognised in the train of the great class of acute and infectious diseases the greater part of my task is accomplished, for not many others than these can be affirmed to have true sequels.

Taking the whole class of *Nervous Diseases* we can find but few remote consequences which can fairly be regarded in the light of sequels. Imperfect recovery may lead to recurrence, and the onset of new symptoms for the most part betokens further progress in any such morbid process, strange and unconnected with the original disorder as they may appear to be. The sequels of chorea commonly depend on renewed activity of rheumatic processes in other parts of the body, and relapses are frequent. Caleb Parry stated that the worst case of spasmodic wry-neck he ever met with followed chorea. This must be a very rare sequel.[8]

We may note the onset of a form of riotous arthritis as a sequel sometimes in cases of syringo-myelia, a condition singularly akin to the arthropathy described first by Charcot in cases of tabes dorsalis.[9] Sufferers from megrim and chronic headache, especially females, are sometimes in middle life and later the subjects of xanthelasma in the eyelids. A happy and frequent sequel of hemicrania is an immunity from it after middle life, so that sufferers cease to be its victims even when subjected to conditions which formerly and unfailingly provoked it. Certain varieties of zona have sequels, some of which are not unimportant. Supra-orbital zona may, especially if the nasal branch of the nerve be involved, lead to ulceration of the cornea, iritis, photophobia, conjunctivitis, partial ptosis of eyelid (involvement of third nerve), defective vision temporarily, or even permanently, with papillary atrophy.[10] Troublesome neuralgia may ensue. This variety of zona is further remarkable for leaving indelible scars behind it. Necrosis of the alveolar part of the lower jaw, with loss of several teeth, was noted by Paget as a sequel of infra-maxillary zona.[11] Sir Thomas Watson's cases are noteworthy; in one, a patient who had been annoyed with continual noises in his head for seven years, became free from them for eighteen months subsequently to an attack of zona of the scalp; in another, a chronic teasing cough disappeared on the supervention of zona. The worst sequel is that of terrible and rebellious neuralgia, which more especially plagues elderly subjects who have suffered from herpes zoster. This may last for months or even for ten or fourteen years, as in cases described by Trousseau[12] and Watson.[13] Injuries to nerves may be followed by vesicular and bullous eruptions and by glossy condition of skin. The sites of former zonal eruptions may subsequently become anæsthetic, hyperæsthetic, or pruritic. Pigment may also be removed from adjacent areas of the integument. An attack of herpes limited to the foot has been reported as following a twist of the ankle-joint.[14]

As bearing on the subject of neuro-trophic lesions and sequels I may refer to two cases within my knowledge where the hair from every part of the body was permanently lost in two male adults after injury to the head caused by violent concussion.[15]

Not many sequels are recognised after the occurrence of diseases of the *respiratory system*. An attack of pneumonia sometimes appears to predispose patients to subsequent attacks. Bronchitis sometimes evokes attacks of spasmodic asthma, which might possibly never have supervened but for the original disorder. We may regard the fatty and lardaceous changes in the liver following on pulmonary tuberculosis as varieties of sequels or consequential degenerations, the latter change ensuing more especially upon prolonged purulent discharge from vomicæ. Neglected and inadequately treated empyemata commonly lead to this condition. Lardaceous change is certainly less frequently met with now than formerly, probably because suppuration is better controlled by modern surgical methods of treatment. We may note the occurrence of rheumatoid affections and of cerebral abscess as pyæmic sequels to bronchiectasis, a condition now also better understood and treated than formerly. We should hardly be justified in regarding fatal hæmoptysis in cases of chronic phthisis, due to aneurysm of a branch of the pulmonary artery, as a true sequel, or the occurrence of tuberculosis as an apparent outcome of an attack of pneumonia. We should have to prove that the original process was not a tuberculous invasion. We may, however, certainly regard as a sequel the occurrence of neuralgia of branches of the fifth nerve supervening on severe attacks of coryza. Respecting pleurisy, whether dry or with more or less effusion, we may still seek to discover whether, when it arises on the right side, it is more commonly the precursor, if not the first step, in the progress of pulmonary tuberculosis. Left-sided pleurisies appear to be more commonly benign in character. This is an old doctrine of the French school and was taught at Edinburgh in my time, and I think there is something to be said in support of it. Many cases presenting strumous adenoma are void of tuberculous symptoms in after-life. Others develop pulmonary tuberculosis, or in advancing years, under the stress of acute

illnesses, become the subjects of new and revealing developments of senile scrofula. Amongst the sequels of chronic nasal catarrh, and often aggravating the condition, are post-nasal adenomata, polypi, and enlargement of the tonsils. Pneumonia may sometimes have a very untoward sequel in the form of pneumococcal endocarditis with a fatal issue therefrom. A case of this kind occurred lately in the practice of my colleague, Dr. Church, and death occurred with sudden onset of anginal symptoms owing to plugging of the coronary artery by the new growth from one of the aortic valves. Osler has found that pneumonia is an antecedent of malignant endocarditis in 25 per cent. of all cases of that disease.[16] Disseminated cerebro-spinal sclerosis has also been known to follow in the train of pneumonia.

Nothing very definite can be affirmed respecting consequences of *diseases of the heart and bloodvessels* which may not rightly be regarded as evolutionary manifestations to be expected in accordance with our modern knowledge of them. We may note the fact that the subjects of congenital cardiac malformation, even when viable to the period of puberty, never attain mature growth, and are bad subjects for the exanthemata, especially for the invasion of scarlatinal poison, and are often prone to be tuberculous. A similar stunting of growth pertains to almost all subjects of endocarditis, with valvular disease, attacked before puberty. Osler remarks that death is due in many cases of congenital heart disease to abscess of the brain. This fact has never been verified in our experience, within my knowledge, at St. Bartholomew's Hospital. Within the last few weeks, however, a case under the care of my colleague, Dr. Church, in which suppurative meningitis occurred, proved fatal. There was no ear disease. There was stenosis by fusion of the three segments of the pulmonary valves, leaving an aperture admitting a swan's quill, and the septum of the ventricles was deficient in the usual situation. The patient was a fairly well developed girl aged sixteen. There was much cyanosis. Headache, several general convulsions, and bilious vomiting occurred for a week before death. The temperature never exceeded 100·6° F. The relation between the cardiac condition and meningitis or cerebral abscess I am quite unable to explain in such cases, and I know of no other author who mentions the connexion but Osler.[17] Insanity sometimes supervenes in cases of aortic and mitral valvular diseases during the stage of compensation, and has been known to lead to suicide.

Ear diseases have sequels which are only too common but now well recognised. I have incidentally alluded to such as occur after the acute infectious fevers. Suppurative meningitis, cerebral or cerebellar abscess, necrosis of the petrous part of the temporal bone, and infective thrombosis of the lateral sinus and internal jugular vein are the chief consequences; and a general pyæmia is not seldom a result, direct infective particles being readily conveyed to the lungs to set up multiple and still further purulent and septic foci of the disease. Prompt surgical measures now, happily, avert many of these terrible sequels. We have further to bear in mind the possibility of otitis media in many patients presenting cerebral symptoms who have no ordinary indications of ear disease as the primary source of this malady.

Respecting the sequels of *gout* I have nothing to note. The many and varied disorders occurring in persons goutily disposed are often distinctly gouty. The several visceral and tissue degenerations observed in grave cases are evolutional manifestations of this disorder. Traumatism, shocks, bodily or mental, or operative procedures may all give rise to outbursts of gout in predisposed subjects and are thus provocative of this revealing symptom.

I may refer to the fact that *adenoid growths in the naso-pharynx* sometimes lead to subsequent tuberculosis, impaired mental functions (aprosexia of Guye), disease of the ear, and to stunted growth of the body. With the activity of modern surgery, which now a days seldom permits these new growths to induce any of these evil conditions, we may perhaps find such sequels of less frequent occurrence in the future. I might add my opinion that operative interference in these cases is not always imperatively necessary.

Such sequels as occur in patients who have been subjected to *ovariotomy* relate rather to physiological than to pathological manifestations. An obese tendency is common, while vocalisation approaching that of the male, growth of hair on the upper lip and chin or over the entire body, loss of general energy, tendency to indulge in stimulants, and proneness to gout have been noted. This is interesting when considered with the commonly asserted statement that eunuchs do not suffer from gout. To these may be added the onset of symptoms of a premature menopause, with flushings, chills, and profuse sweatings. The spleen may, as Mr. Knowsley Thornton informs me, become temporarily enlarged a few months after this operation. He has observed the occurrence of pains in the joints, tendons, and fasciæ, but these have subsided generally within a year or two, but he believes any other changes to be exceedingly rare.

Amongst *diseases of the skin* we may observe the tendency of some scars to become the seats of Alibert's keloid. Long-persisting local irritation may eventuate in the formation of fatty and fibro-fatty tumours, and predispose to malignant growths. Psoriasis may pass into lichen ruber. Chronic tinea capitis may lead to patches of area which, so far as I regard the latter, are neurotrophic and non-parasitic. General dermatitis may supervene on ringworm. Dr. Abraham had an example of this kind under his care. Erythema appeared over the trunk, desquamation of the palms and soles followed, and the skin assumed a xerodermia-like condition with furfuraceous scaliness. Anthrax has sometimes been followed by malignant endocarditis. It is still undetermined whether acro-scleroderma is a true sequel in cases of Raynaud's disease. The association of the two conditions is certain. If we enlarge, as I think we should do, our conception of the state known as Raynaud's disease or local asphyxia I think it is permissible to believe that such cases may sometimes eventuate in a condition of wide-spread scleroderma with telangiectases and acro-sphacelus. I have now under observation in private a grave example illustrating these changes. Lupus may sometimes become the seat of epithelioma, and the inflammatory lupoid ulcerations met with in Kaposi's disease (xerodermia pigmentosa) may also produce cancer. It is not yet determined whether the condition of skin known as Paget's disease of the nipple, scrotum, and penis is a benign form of eczematoid irritation due to psorospermial infection, leading ultimately to cancer, or whether it be, as held by Dr. Thin, cancerous disorder throughout. In most cases of mycosis fungoides there is also a long preliminary stage of eczematoid disease, not seldom mistaken for chronic eczema, urticaria, or erythema, which is followed months or even years afterwards by the special fungating lesions. Sometimes the latter appear without any superficial dermatitis. It is not without interest to know that an attack of erysipelas is alleged to have cured one case of this intractable and slowly fatal disease. A variety of xanthoma, temporary in character, is occasionally met with in the course of chronic glycosuria, probably due to irritation either from glucose or some ill-metabolised matters in the circulation.

The consequences of specific *gonorrhœal* infection are well known in the form of ophthalmia, often incoercible arthritis, especially in those of a gouty habit of body, and in flat-foot. The toxine generated by the gonococcus may sometimes prove very virulent. Whether it be generated directly by this organism or whether, as in the case of diphtheritic bacilli as shown by Dr. Sidney Martin, it arises from a chemical substance of the nature of a ferment, which acts upon albumoses in the body and converts them into a toxine, is not yet ascertained; but it has been suggested by Dr. Gowers that this may in some cases alight upon the nervous structures as it does in others upon joints, and so set up a rapidly spreading myelitis which has sometimes proved a fatal sequel of gonorrhœa. Dr. Gowers has described a case of this kind which ensued three weeks after primary infection and one week after convalescence. The patient was an overworked youth of nineteen years of age. Gonorrhœa in youth appears to predispose to urethral stricture at a period of life when prostatic changes set in. Dr. Hale White has recorded two cases in which malignant endocarditis resulted from gonorrhœal virus, the pulmonary valves being affected in each case.[18] Pericarditis, pleuritis, and peritonitis are also amongst recognised sequels, and gonococci have been found in the pus of gonorrhœal ophthalmia and may probably be discoverable as the cause of the iritis which is often associated with it. In women ovaritis and chronic pyo-salpinx may follow gonorrhœa.

Obesity is sometimes a sequel of acute illnesses and is especially frequent after enteric fever and pneumonia.

[16] Other experience does not support this observation.
[17] Principles and Practice of Medicine, second edition, 1895.

[18] THE LANCET, Feb. 29th, 1896, p. 534.

Digitized by Google

Anæmia, hæmorrhagic or otherwise, may also be followed by obesity, and the same condition has been observed to develop after courses of mercury.

There are no very noteworthy sequels in the train of *diseases of the alimentary system*—none, that is, in the sense in which I have considered them in these lectures. Most consequences of these disorders relate to renewed attacks or are of the nature of complications and direct extension of morbid processes. I may mention the occurrence of tetany as sometimes following cases of gastrectasia, especially after the stomach has been washed out (Kussmaul). In cases of chronic indigestion in young children, described as the "cœliac affection," or diarrhœa alba, by Dr. Gee,[19] when recovery is slow there is apt to remain a frail condition of health, with stunting of growth and a weakness in the limbs, the child being unable to jump. Leucoma, psoriasis, syphilitic ulcers, and all varieties of irritation of the tongue are amongst recognised conditions which may eventuate in the sequel of carcinoma at some later date. Gastro-intestinal catarrh has been observed in one case to be followed by paresis of the lower extremities, according to M. Potain, and the same authority has described a case of secondary spinal paralysis which followed chronic diarrhœa. Right hemiplegia with anæsthesia has been also noted in the course of gastro-intestinal catarrh. It is not improbable that some febrile disorders as yet not differentiated may arise from absorption into the system of toxalbumens from the alimentary canal. Mr. Macnamara has suggested that septic products due to many carious teeth may thus sometimes exert pernicious effects, including some forms of painful arthritis.

Hepatic diseases.—The vagaries and symptoms set up by gall-stones are fully appreciated and tend to many and strange sequels—biliary fistulæ, pyrexia, catarrhal cholangitis, and intestinal obstruction amongst many others. Some of the most difficult diagnostic problems, clinical mysteries, come to be solved by the presence somewhere of biliary calculi. In a considerable number of cases carcinoma is the outcome of their continued irritation, arising in the gall-bladder or gall-ducts and gradually invading the liver texture and even spreading generally to the abdominal lymphatics, the lungs, peritoneum, and omentum. Biliary calculi being more frequently present in women this grave sequel is rather more common in them. Dr. Norman Moore met with ten examples of cancer of the gall-bladder and large bile-ducts, five in each sex, all of carcinoma. Gall-stones were present in four and a calcified hydatid cyst in one.[20] The occurrence of xanthelasma may be mentioned as an occasional sequel of chronic jaundice. In several cases of hepatic abscess I have known the patient to suffer from recurring pain in the region of the liver, evidently due to adhesions. This has been severe enough to arouse fear of a fresh abscess. In one case an officer could never comfortably bear the weight of his sword when doing duty on his horse. In another case death occurred within two years owing to adhesions between the liver, stomach, and adjacent parts, the original abscess, a very large one, having long been healed. No operative measures would have been of any avail.

Diabetes cannot be said to have any sequels, properly so called. The conditions of glycosuria as a manifestation of gouti ness, the result of faulty metabolism in intestinal digestion or of hepatic inadequacy, is one which induces a general faulty nutrition and a vulnerability of the tissues of the body, which may expose the patient to special dangers under the stress of acute diseases, or render him especially liable to tuberculosis, boils, carbuncles, and gangrene. A saccharine impregnation of the blood appears to render that fluid a better medium for the cultivation of microbes.

Animal Parasites may lead to several untoward sequels. Thus, the blood-flukes—Bilharzia hæmatobia—as a cause of endemic hæmaturia may form nuclei for the formation of vesical calculi and also induce a form of dysentery. Distomata, or liver-flukes, may lead to cholangitis, hepatic enlargement, jaundice, and ascites. Lumbrici may pass into the larynx or trachea, causing suffocation or gangrene of the lung, or they may enter the common and also the smaller bile-ducts. The bowel may also be perforated by them and peritonitis result. Trichiniasis, when recovered from in the acute stage, may leave behind it great muscular weakness, lasting for months, or, as in one case, for eight years. Filariasis may lead to a form of intermittent hæmatochyluria lasting for many years.

[19] St. Bartholomew's Hospital Reports, vol. xxiv., 1883, p. 17.
[20] Bradshaw Lecture, Royal College of Physicians of London, 1889.

The condition of *Anæmia*, apart from the pernicious variety, has but few sequels. It is commonly recovered from, and women who have suffered at one time from chlorosis are subsequently found to have good health and to bear children satisfactorily. In certain neglected cases, cardiac dilatation leading to grave symptoms may ensue, but adequate, that is prolonged, treatment should avail to avert any such sequel. As a constitutional condition, however, we may, I think, affirm that anæmia distinctly leads to gastric ulceration. It is certainly uncommon to meet with this disease in either sex if the patient's blood is of due corpuscular richness and adequate in respect of hæmoglobin. We may not accept the opinion that anæmia is the cause of Graves' disease, although there is not seldom some degree of this present, occasionally induced, as it would appear, by rebellious and intractable diarrhœa. I agree with Trousseau that many cases of anæmia require treatment extending over three years.

Ren mobilis.—Displacement of the kidney may lead to several troublesome consequences of which pain at the menstrual periods is a frequent one. Occasional strangulation of the vessels and ureter may occur, leading to hæmaturia and to occlusion by kinking of the ureter with temporary hydronephrosis. The hepatic flexure of the colon is apt to suffer by contiguity to the right and commonly displaced organ, and sometimes irritation is set up which ends in the establishment of adhesions between this part of the bowel and the kidney. Fears may thus come to be entertained of serious new growth in the colon, owing to localised pain, sense of fulness and resistance, and symptoms of partial obstruction of the bowel.

Renal diseases.—There are no recognised sequels of diseases of the proper structures of the kidneys which cannot be readily explained by the natural outcome and influences, far reaching enough as they are, of the original disorders of these organs. We are as yet, however, in ignorance of the ultimate clinical history of cases which we often meet with, known as examples of albuminuria of adolescents or cyclical albuminuria. We know that many persons so affected ultimately recover, but we wait for knowledge of the life histories of many more in order to be able to frame a prognosis for them and to direct the management of such cases. Paroxysmal hæmoglobinuria is met with sometimes in persons subject to Raynaud's disease, though not as a sequel. In my opinion, the former is sometimes but a phase of the latter state. Hæmoglobinuria of the toxic variety, due to dissolution of the blood-corpuscles, is sometimes witnessed as the result of the specific infectious fevers, such as scarlatina, variola, yellow fever, enterica, malaria, and syphilis.

Chemico-toxic Sequels.—Dr. Alexander Scott of Glasgow has recently recorded a case of poisoning by carbon monoxide vapour in which a form of dementia resulted with occasional and partially lucid intervals, and he tells of a similar case reported by Stockes of Lucerne.[21] The symptoms continued for three months up to the time of recording the case in Dr. Scott's patient, and in the other case were present two years after the poisoning. Slight but very slow improvement occurred in both instances. The explanation afforded is to the effect that the carbon monoxide combines with the hæmoglobin of the blood, forming a very stable compound, carboxyhæmoglobin, which will neither diffuse nor dissolve and which resists oxygenation. The nutrition of the body thus suffers, and in particular that of the brain and nervous system, with the induction of long abiding mental and other symptoms. Carbon monoxide may also lead to one variety of toxic hæmoglobinuria. As examples of other chemico-toxic sequels we have the ultimate effects of arsenicism in producing melasma, zona, and peripheral neuritis; œsophageal stricture and acute tuberculosis following the action of corrosive poisons; gout supervening on plumbism; saturnine nephritis, neuritis, and encephalopathy; tabes sicca from zinc impregnation; skin discolouration from silver salts;[22] tremor from mercurial poisoning; and neuritis caused by alcohol and by bisulphide of carbon.

Lastly, amongst favourable sequels may be mentioned the rare occurrence of involution or withering of malignant growths. This is met with in old persons in whom cancer often remains almost stationary. Dr. Robert Liveing and

Mr. Morrant Baker had under their care a case of fibro-sarcoma of the scalp in a young man aged twenty-four years which slowly underwent involution. When last seen four years later the process of atrophy had greatly exceeded that of growth.[23]

Having now discussed so far as I am able the various consequences and sequels of diseases—some of which may possibly have been wrongly interpreted or summoned and alleged to do duty for them by reason of the mental temper which always besets an eager inquirer into any particular set of circumstances—I may sum up my efforts by endeavouring lastly and concisely to classify, in accordance with the most recent knowledge available, the sequels that have come under notice. I mentioned at the outset of these lectures that a distinction should be made between complications, even late ones, of diseases and the sequels of them. I have tried to make this distinction, but it has not been quite an easy matter to do so. We are strictly concerned with the consequences of disease, or, in other words, the diseases of convalescence. A consideration of the whole group of acute infectious diseases, which furnishes the greater number by far of those which have sequels, shows up this difficulty very strongly, for we have found that most of these consequential troubles owe their existence to specific residual infective elements which have lain dormant or more or less latent within the body, giving rise either to early or late sequels. These are, therefore, to be termed bacterio-toxic or microbic sequels. Of these we have examples in the various fevers, in diphtheria, influenza, malaria, and syphilis. We have seen that these may be manifested very variously in different organs and parts of the body. When affecting the nervous system they lead to central or to peripheral symptoms, according to the locality involved. With these we sometimes find associated sequels dependant on fresh invasion by microbic elements non-specific of the primal disease, but which are ever ready either within the system or outside of it to alight upon parts that have recently been rendered vulnerable by pre-existing morbid processes. These I term indirect sequels. We have seen that certain acute diseases sometimes reveal diathetic proclivities hitherto little marked or even dormant, as in the cases of gouty or strumous habits of body, or which, as in the case of syphilitic taint, awaken long latent residues and so evoke revealing symptoms of unexpected character. These I term revealing sequels.

The debility and diminished tissue-resisting powers of the body induced by acute diseases or by exhausting influences and low state of health open the door to fresh invasion from within or from without, and in this way invite new sequels and often a succession of diseases. So-called "surgical scarlet fever" is, without doubt, an instance of true infection by that specific disorder to which patients are particularly prone after the shock and wound of an operation, owing to the vulnerability and susceptibility thus induced. Traumatism of any kind is apt to be followed by revealing symptoms of some constitutional tendency or taint. Thus, we have instances of puerperal septicæmia set up by invasion of varieties of specific and toxic microbes. We meet with cases in which tuberculosis awakens and rages after injuries to the head and other parts of the body, such as joints, and we have already noted the occurrence of erysipelas as an attendant on traumatism. We may take note of the diathetic and local determinants which materially affect the original incidence and the sequels of diseases. Weak points are attacked, areas of special vulnerability, and organs and parts whose functions are inherently inadequate—*loci minoris resistentiæ*. We perhaps too little regard the frailties of particular organs and tissues, frail by inheritance and prone to premature failure and decay, although adjacent to other and more robust portions of the frame of the individual; for likeness of organs and tissues goes by descent, as does mere likeness of features. Hence many puzzling conditions and surprises in the study of diseases. But the clinical physician must take note of such. *Nervous sequels* relate chiefly to neuro-trophic disorders and neuralgia. *Sequels due to chemico-toxic influences.* Respecting many of these, we have to note the fact of symmetrical or bilateral nervous affections due to general impregnation of the system through the blood.

[23] Catalogue of the Anatomical and Pathological Museum of St. Bartholomew's Hospital, vol. iii., 1881-93, p. 383.

DISEASES OF CONVALESCENCE AND SEQUELS OF DISEASES.

Complications of Diseases.—(*a*) Early, (*b*) late. Incomplete convalescence.

Sequels.—1. *Bacterio-toxic:* (*a*) Early, microbic, or germinal, with short latency; (*b*) late, microbic, or germinal, with longer latency; residual diseases; ultimate evolutions or manifestations of the original disease; (*c*) direct, specific of the primary disease; (*d*) indirect, induced by the primary disease, but due to fresh or secondary infections by new toxines—(*a*) already present in the body, or (*b*) newly introduced from without (mixed infections), hence succession of diseases. 2. *Revealing:* Determinative of manifestations of constitutional habits of body or of inherited or acquired specific (? germinal or particulate) taint. 3. *Nervous:* Neurotrophic, neuralgic. 4. *Chemico-toxic:* Arsenic, lead, mercury, silver, carbon monoxyde, corrosives. 5. *Direct*, non-toxic: *Residual* sequels, &c.; Residual sequels probably determined to certain localities by tissue-predisponency—(*a*) inherited, or (*b*) acquired by previous injury—*loci minoris resistentiæ*.

We have found that most sequels of diseases are an increased burden for the patient, but we have also noted that a few of them are even favourable and happy. The great fact remains that the majority of sufferers from all manner of diseases are not the victims of sequels, and that for this majority the course of their maladies, when not directly fatal, is singularly and fortunately free from any important consequences. A study of the subject of the sequels of diseases cannot, however, fail to impress upon all of us who are actively engaged in treating patients during their illnesses the supreme importance of steadfastly regarding the patient, and not so much his disease, in all our therapeutic management. To conduct the patient prudently and safely through his troubles, to realise how he bears them and what they mean or may mean to him, to gauge his powers of tissue resistance and his reserves of vital power, to have regard to his mental condition and to all his particular environments, and to secure sound convalescence, is as far as possible to avert the worst consequences, early or remote, of the particular malady in progress. This, and no less than this, is the duty which lies before each one of us, and to carry it out effectually demands the best qualities both of head and heart that we can place at the disposal of our patients. And such qualities, Sir, I venture to say, have not been wanting in the lives and work of the majority of the great and good men who have adorned this venerable college and left us the legacy of their skill and of their characters; who have, no less, left us under the responsibility of maintaining here, as the Physicians of England, the highest standards of work, of duty, and of professional honour. May we try to be worthy of our predecessors. We can hardly surpass them in any of these qualities.

It only remains for me to offer to you, Sir, and to this auditory, my best thanks for the kind attention given to me in this course of lectures.

A PRELIMINARY NOTE ON

A METHOD FOR RAPIDLY PRODUCING DIPHTHERIA ANTITOXINS.[1]

BY G. E. CARTWRIGHT WOOD, M.D., B.SC. EDIN.

THE method for producing antitoxins described in this preliminary communication is the outcome of an investigation into the action of the products of the diphtheria bacillus on which I have been engaged for more than a year.[2] The toxines described by Continental observers have been those obtained from broth cultivations of the organism, where we cannot expect the products, even if identical in nature, to be present in the same proportions as when vegetating in the living body of an animal. More than eight

[1] A paper read before the Royal Society on Feb. 20th, 1896. (Communicated by Dr. Pye-Smith, F.R.S.)

[2] The investigation has been carried out in the laboratories of the Royal Colleges of Physicians of London and Surgeons of England, and I should like here to express my great indebtedness to the Laboratories Committee for the facilities they have afforded to me. I must also thank them and, through them, the Honourable Goldsmiths' Company, from whose Research Fund a grant was placed at my disposal.

years ago Hueppe[3] and I pointed out that we must grow the pathogenic organism on a natural albumin if we wished to obtain the toxines proper of the microbe; and working on this principle by inoculating hens' eggs with Koch's cholera bacillus we succeeded in producing much more powerful poisons than had been previously obtained. The toxines produced by the action of the diphtheria bacillus on albumen have been minutely investigated by Sidney Martin, and the occurrence of the same substances in the bodies of patients who have succumbed to the disease has proved the correctness of this view. In this communication I shall not enter into the precise nature of the products in question as my present purpose is to describe a practical method of rapidly producing powerful diphtheria antitoxins.

In these experiments two species of diphtheria toxine were made use of: firstly, the ordinary toxine produced by the organism in peptone broth; secondly, the substances present in serum broth cultivations which had been filtered and heated up to 65°C. [In the former the active principle consists almost entirely of the so-called ferment toxine, while in the latter this has been destroyed by heating up to 65° C. so that its action must depend on the presence of other substances.[4]] The medium employed for the production of the serum toxine was ordinary peptone broth, to which an addition of 10 or 20 per cent. blood serum or plasma had been added; where the latter was used the broth was previously decalcified to prevent coagulation. As a rule the broth was inoculated with a virulent diphtheria culture some three or four days previous to the addition of the serum or plasma and then incubated at a temperature of 37° C. for at least three or four weeks. Before being used for injection it was subjected to a temperature of 65° C. for about an hour and then filtered through a sterilised Chamberland candle to remove the bodies of the bacilli. This fluid will be spoken of subsequently as "serum" toxine in contradistinction to the ordinary poison, which will be spoken of as "broth" toxine. The serum toxine is characterised chiefly by giving rise to little local irritation but to marked febrile reaction, which is still more pronounced when the injection is repeated. As the diphtheria albumose described by Dr. Sidney Martin was characterised by precisely these properties, in all probability the potency of the serum toxine depends on its presence. In addition to these properties, however, it was found that animals which had been subjected to its action were rendered more or less refractory to subsequent infection, and this suggested the possibility of its application as a means of shortening the preliminary treatment which a horse must undergo before it can receive the large doses of broth toxine which are usually necessary for the production of antitoxin of any strength.

The first horse (No. 1) was treated on the same general principles which are adopted in immunising guinea-pigs—that is to say, it received a certain quantity of the "vaccinating" substance and after the elapse of ten or fourteen days it was subjected to the action of the microbe or toxine. During the first twelve days this horse received 380 c.c. of serum toxine spread over three injections on different dates. The temperature (starting at 9·25° F.) rose on the second day to 100·25° F. after the first injection (120 c.c. serum toxine), falling on the third day to 99·25°. On the fifth day, when 150 c.c. of serum toxine were injected, the temperature rose till it attained on the sixth day 101·75°, falling to 98·75° on the twelfth day, when 110 c.c. of serum toxine were injected. The temperature rose on the thirteenth day to 102°, falling to 99 25° on the fourteenth day. On the nineteenth day of the experiment it received 50 c.c. of unfiltered serum toxine (sterilised at 65° C.) and 150 c.c. of broth toxine (of which one-half c.c. killed a 500-gramme guinea-pig in forty-eight hours) the temperature rising to 101·5° on the twentieth day. This unfiltered serum toxine unfortunately gave rise to a small abscess which greatly impeded the treatment, and subsequent experience has convinced me that the bodies of the bacilli which gave rise to this irritation must be removed by filtration if the process is to be carried out smoothly and successfully. On the twenty-eighth day with the temperature nearly normal it received 50 c.c. of the same broth toxine, the temperature rising to 100·5°, and on the thirtieth day (temperature 99·4°) another injection of 115 c.c. The horse was then bled on the thirty-second day of treatment, and the serum was found to possess the strength of ten normal units, that is to say, $\frac{1}{100}$ c.c., protected a 250-gramme guinea-pig against ten lethal doses of broth toxine. As this strength is only attained by Roux's method after at least ten weeks' treatment it was evident that the serum toxine had considerably shortened the process. It may be mentioned that the horse which had been in very poor condition at the beginning of the treatment, steadily improved during the month. The experiment was not carried further with this horse, which was then subjected to the ordinary method for producing antitoxins where it reacted in every respect like an animal which had been under the usual treatment for several months.

In the case of the next horse (No. 2) it seemed safe to inject much larger quantities of the serum toxine, but to avoid the risk of constitutionally injuring the animal the addition of a certain amount of antitoxin was made. During the first twelve days 1350 c.c. of serum toxine had been injected, and mixed with this 50 c.c. of antitoxin obtained from the previous horse each c.c. of which contained ten normal units, the temperature never exceeding 101° F. after the injection. During the next week 550 c.c. of broth toxine (of which $\frac{1}{4}$ c.c. killed a 500-gramme guinea-pig in forty-eight hours) was injected spread over three injections, and to the last of these 100 c.c. of serum toxine was added. In the succeeding week it received 400 c.c. of the same broth toxine mixed with 250 c.c. of serum toxine in two injections, the temperature rising next day (twenty-fifth) to 102° F. On the thirtieth day the animal was bled ($\frac{1}{2}$ of a litre) and the antitoxic value of its serum estimated. It was found that $\frac{1}{100}$ c.c., $\frac{1}{800}$ c c., $\frac{1}{300}$ c.c., $\frac{1}{150}$ c.c., $\frac{1}{50}$ c.c., and finally $\frac{1}{1000}$ of a c.c. protected completely against ten lethal doses of the toxine. After six weeks of treatment $\frac{1}{1000}$th of a c.c. protected against ten lethal doses, while on the ninth week $\frac{1}{2500}$th of a c.c. sufficed. In this experiment which furnished such brilliant results, as has been stated, antitoxin was mixed with the serum toxine injected, but that this was not at all necessary was shown by a subsequent experiment, in which another horse (No. 3) received no less than 2180 c.c. serum toxine in the space of a fortnight without any apparent injury. The serum of this animal was tested during the first and second weeks, before it had received any broth toxine, and it was found that $\frac{1}{300}$ c.c. and $\frac{1}{100}$ c.c. respectively protected guinea-pigs against ten lethal doses. On the third week $\frac{1}{800}$ c.c. protected, and at the end of a month $\frac{1}{1250}$ c.c. sufficed. [The large amount of antitoxin produced during the first two weeks, when the horse received serum toxine alone, was quite unexpected, and leaves still unsettled the question as to how far the acquired immunity produced by the serum toxine is due to increased tissue resistance or to the presence of the antitoxin in the fluids of the body.] These results are shown in Table I. (horse No. 3).

TABLE I.—*Horse No. 3.*

—	Antitoxic value of serum.	Amount of toxines injected.
7th day	$\frac{1}{250}$ c.c.	1200 c.c. serum toxine.
14th day	$\frac{1}{50}$ c.c.	980 c.c. serum toxine.
21st day	$\frac{1}{125}$ c.c.	650 c.c. serum toxine and 1050 c.c. weak broth toxine.
28th day	$\frac{1}{1250}$ c.c.	1100 c.c. serum toxine and 1200 c.c. stronger broth toxine.

Although the serum toxine had been used primarily in the expectation of rapidly immunising the animal and thus shortening the necessary period of treatment, the very high antitoxic value of the serum obtained from horses Nos. 2 and 3 suggested that the method might be applied effectively at a later stage. For the purpose of testing this a number of horses which had been under the ordinary treatment for from six to nine months were very kindly placed at my disposal by the Director of the Laboratories, Dr. Sims Woodhead. In the first experiments 200 or 300 c.c. of the serum toxine was mixed with the ordinary broth toxine, and injected as usual. The results obtained, although slightly better, were not at all so marked as one might have expected. On examining more in detail the horses in which the best results had been obtained it was found that these had been under more or less continuous treatment with the serum toxine, both toxines being

[3] Centralblatt für Bakteriologie, No. 5, 1884.
[4] The passages in brackets were added after the reading of the paper.

Digitized by Google

injected as frequently and in as large amounts as possible. Guided by these facts four of the horses (Nos. 4, 5, 6, 7) received one evening each 300 c.c. of serum toxine and on the following morning an injection of weak broth toxine. Although the quantity of weak broth toxine would under normal conditions have produced hardly any effect it produced on this occasion most marked local and constitutional reactions. During the remainder of the week these horses received injections of weak broth toxine each day or on alternate days according to their condition, and on each occasion these gave rise to quite definite constitutional and local reactions. During the following week an injection of 300 c.c. of serum toxine was introduced, succeeded by similar quantities of weak broth toxines, as in the previous week. [It will be observed that all these horses received practically the same quantities of toxine, with the exception of horse No. 5 in which the injections were stopped earlier than the others owing to its temperature showing a tendency to remain permanently elevated. In horses Nos. 6 and 7 the production of antitoxine was much less than in Nos. 4 and 5, and this is, no doubt, to be ascribed to the injections producing much less marked reactions owing apparently to their greater refractoriness. In all probability, however, this condition might have been overcome by the use of larger injections and stronger broth toxine.] The rise in antitoxic value of the serum of these horses is shown in Table II.

TABLE II.

—	Strength of serum before treatment.	Strength of serum after sixteen days' treatment.	Amount of toxines injected during the sixteen days.
Horse No. 4 ...	$\frac{1}{500}$ c.c.	$\frac{1}{2000}$ c.c.	650 c.c. serum toxine and 2350 c.c. weak broth toxine.
Horse No. 5 ...	$\frac{1}{50}$ c.c.	$\frac{1}{1000}$ c.c.	600 c.c. serum toxine and 1800 c.c. weak broth toxine.
Horse No. 6 ...	$\frac{1}{50}$ c.c.	$\frac{1}{750}$ c.c.	650 c.c. serum toxine and 2350 c.c. weak broth toxine.
Horse No. 7 ...	$\frac{1}{100}$ c.c.	$\frac{1}{750}$ c.c.	650 c.c. serum toxine and 2350 c.c. weak broth toxine.

These results indicate very strikingly that the rapid production of antitoxin depended at any rate in great part on the "cumulative" action of the toxines by means of which the animal was kept in a chronic condition of local and constitutional reaction. It is probable that we produce in this way the earlier stages of that condition of "supersensitiveness" described by Behring, in which an animal whose blood may be charged with the most powerful antitoxins suffers the most profound constitutional disturbance on the introduction of even the smallest quantities of toxine while at the same time the temperature of the animal may remain for months permanently elevated above the normal. By taking advantage, however, of this cumulative action in its earlier effects we are furnished with a means of easily producing much more powerful antitoxins than is otherwise possible, and it is probable that by the use of stronger broth toxine the method may be carried still further in this direction. This cumulative action may also be taken advantage of to obviate that most troublesome occurrence where an animal becomes apparently absolutely refractory, ceasing to react to the toxine and failing to produce antitoxin, so that it has to pass out of use for the purpose of producing the curative serum. Some preliminary experiments have, however, indicated that this cumulative action may be produced still more markedly by the use of other toxines than those elaborated by the diphtheria bacillus, a result which I was quite prepared for, as Woodhead [5] and myself had in a previous communication drawn special attention to this "summative" action of bacterial products.

Although this part of the investigation is still quite incomplete, an application of this principle which may be of importance may be here suggested. The excessively costly nature of snake venom and the practical difficulties of obtaining it in sufficient quantities have been a great obstacle to the immunisation of the larger animals or the production of "anti-venines" of any high degree of strength. It is probable that by the use of other toxines in the later stage the quantities of the costly snake venom necessary may be greatly lessened.

[In this preliminary communication I have dealt with horses which have been under treatment only for a short period, and have shown that antitoxins at least as strong as the best in use can be quickly and easily produced, but I have every reason to believe that under more prolonged treatment much more powerful diphtheria antitoxins can be obtained than has been previously possible.]

In conclusion it may be said that the following advantages may be claimed for the use of the toxines in the way I have described. 1. That powerful diphtheria antitoxins can be produced without risk in a much shorter period of time than has been previously possible. 2. That much more powerful antitoxins can be easily produced so that the amount necessary to be injected into a patient can be greatly reduced, and one of the great objections to its introduction into private practice in this country may be removed. 3. That the greater strength of the serum will permit of the patient receiving at the beginning of treatment a sufficient quantity of the serum at one injection when, as is universally recognised both by animal experiment and clinical experience, its curative action is exerted most markedly.

I must acknowledge my extreme indebtedness to the Director of the Laboratories, Dr. Sims Woodhead, for much invaluable advice and assistance during the course of this investigation.

THE RÔLE OF THE STREPTOCOCCUS PYOGENES IN HUMAN PATHOLOGY.

BY WILLIAM BULLOCH, M.D. ABERD.,
BACTERIOLOGIST IN THE BRITISH INSTITUTE OF PREVENTIVE MEDICINE.

IN 1880 Ogston [1] described the presence of streptococci in the pus of abscesses. In the fifteen years that have passed since then, our knowledge of the micro-organism has gone forwards by leaps and bounds. Its practical importance as a cause and concomitant of disease has correspondingly increased. Isolated workers have chronicled their observations, but unfortunately these observations to a large extent remain isolated. Therefore it seemed desirable to give a brief *résumé* of our present day knowledge, especially in consideration of the successful attempts which have been made in the treatment of streptococcic diseases. The introduction of the culture methods by Koch enabled Rosenbach [2] (1884) and Passet [3] (1885) to make a more complete study of the streptococcus. In the meantime, however, Fehleisen [4] (1882) had described the occurrence of chain-cocci in erysipelas under the name of "streptococcus erysipelatis." Extended observation soon demonstrated the presence of streptococci in many different pathological conditions, and to these cocci specific names were given, such as the streptococcus septicus of Nicolaier,[5] the streptococcus septo-pyæmicus of Biondi,[6] and the streptococcus pyogenes malignus of Flügge.[7] However, the opinion now almost universally held is that the grounds upon which these distinctions have been founded are insufficient and that there is but one species of streptococcus which plays a part in human pathology—viz., that generally termed "streptococcus pyogenes." The identity of the streptococcus pyogenes (Rosenbach) with that found in erysipelas and in puerperal fever was first affirmed by Widal,[8] whose position has subsequently been fully supported by Verneuil and Clado,[9] E. Fränkel,[10] Achalme,[11] and

most recently by Petruschky[12] and Marmorek.[13] The differentiation into species probably arose from the number of varieties of pathological lesion in which chain-cocci are found. Clinical and experimental evidences unite to show that diversity of lesion may be explained otherwise than by the presupposition that the infecting micro-organisms differ in species. There are four main factors the variations of which determine the nature and extent of streptococcic lesions. 1. The first and most important of these factors is the extraordinary variability in the virulence of the microbe. Starting from a streptococcus harmlessly inhabiting the buccal cavity we may pass experimentally through all stages till we obtain an organism of such exalted virulence as to be capable of producing a rapid and general infection (bacteriæmia). Any one of such experimental lesions finds its parallel in human pathology. 2. A variation in the site and depth of the infection produces a difference in the nature and severity of the lesion; this seems to explain why at one time an erysipelas is developed and at another time a phlegmon. 3. Varying resistance on the part of the body is the third factor in the production of a diversity of lesion; witness the severe streptococcic lesions met with in advanced cases of diabetes and Bright's disease. 4. The association of the streptococcus pyogenes with other microbes, pathogenic and non-pathogenic. These associations or "mixed infections" I propose, following the nomenclature of Verneuil, to call throughout this paper "polymicrobic infections."

The wide distribution of the streptococcus pyogenes renders it difficult in certain cases to determine what has been the immediate source (*Herkunft*) of the infecting cocci. Undoubtedly in a great number of cases an exogenous infection must be assumed. In the polymicrobic infections, however, while this mode of origin cannot be excluded, it is quite possible that the secondary streptococcic infection may be from cocci normally inhabiting the skin or mucous membranes (endogenous infection) and leading a saprophytic existence there under normal conditions. There are two further possibilities: (1) that the virulence of the streptococcus pyogenes is exalted by being associated with other microbes, pathogenic (e.g., bacillus typhosus) and non-pathogenic (experimentally bacillus prodigiosus); or (2) that the apparent exaltation is really an expression of a diminished resistance on the part of the body caused by the primary infection. In some of the polymicrobic infections both factors seem to be at work; in others only one. In most cases the primary coccic lesion can be determined, but there occur cases of generalised infection where after the most careful investigation the point of entry cannot be ascertained. For convenience such cases have been called by Jürgensen, Leube, and others "cryptogenetic infections." A strepto-mycosis (any streptococcic infection) is at first essentially a local process. It may remain local, giving rise to an erysipelas or a phlegmon, or it may become generalised, a condition ordinarily designated "streptococcic pyæmia," but better called "metastatic strepto-mycosis." The streptococcus gains access to the blood stream directly or indirectly by gradually working its way along the lymph paths, producing lymphangitis, inflammations of serous membranes, &c., and eventually entering the general circulation. These varieties of localisation occur in the polymicrobic as well as in the monomicrobic infections.

Erysipelas.—This affection is an ideal example of a strepto-mycosis. Jordan[14] has recorded cases where the staphylococcus pyogenes aureus was found in company with the streptococcus, but it is a question whether these were not cases of polymicrobic infection, the staphylococci gaining entrance after the commencement of the erysipelas. Although mainly a local disease the general symptoms are probably in some cases caused by a coccic invasion of the blood as demonstrated by von Noorden[15] and others. The local lesion is a dense small-celled infiltration. The cocci are found for the most part in the lymphatic spaces and vessels of the corium. The bloodvessels are as a rule free. Towards the edge of the red area the fibres of the cutis are œdematous and the lymph vessels contain numerous cocci. The cessation of the redness on the fourth or fifth day is due to the rapid disappearance of the infiltration by a process of fatty degeneration. While one part undergoes resolution a new part is, however, invaded. As regards the coccic distribution the erysipelatous lesion may be roughly sub-divided into three main areas from centre to periphery. 1. The area of resolution, where the process is beginning to subside; the cocci are comparatively few in number and in some places have entirely disappeared. 2. The area of active inflammation corresponding to the red part; there the streptococci are abundant in the lymph spaces and vessels. 3. The area of commencing coccic invasion, which extends for a short distance peripherally to the red area; the cocci are numerous and inflammation is just commencing. In severe fatal cases the general lesions are cloudy swelling of the kidney, liver, spleen, cardiac muscle, and pyogenic endocarditis. In such cases the streptococci have entered the general blood system and they may be found in pure culture in all the viscera (Hartmann,[16] Pfuhl,[17] and Petruschky). Metchnikoff[18] has affirmed that in favourable cases the streptococci are to a very large extent destroyed by phagocytes; while in fatal cases no phagocytosis was found when the micro-organisms had become generalised. The severity of the lesion in any given case of erysipelas depends for the most part on the degree of virulence of the streptococci. There is also distinct evidence that in man, as is seen experimentally in rabbits, the passage from one individual to another in epidemics of erysipelas exalts the virulence of the streptococcus, the later cases being more severe than the earlier ones.

Phlegmon of the skin (pseudo-erysipelas).—Phlegmon of the skin, although not necessarily always caused by the same organism, has very frequently the streptococcus pyogenes for its cause. Here, in contradistinction to erysipelas, there are progressive suppuration and breaking down of the tissues. The pyogenic chain-cocci rapidly invade the lymphatics of the subcutaneous tissues and set up a streptococcic lymphangitis and lymphadenitis. If the suppuration extends deeply there is great danger of purulent thrombo-phlebitis and general strepto-mycosis.

Pyæmia and septicæmia.—The general conditions following the introduction of the streptococcus into the blood are those which are loosely described under the collective names of "pyæmia" and "septicæmia." The terms "sepsis" and "septicæmia" were originally used to denote certain morbid conditions caused by *putrefactive* blood poisoning. Later, Davaine and Koch used the word "septicæmia" for certain microbic blood infections where the microbes multiply in the blood and cause a rapidly fatal disease. Anatomically it is distinguished from pyæmia by the absence of metastatic purulent deposits. Early in the history of bacteriology micro-organisms were demonstrated to exist in the wounds of pyæmic individuals and also in the metastases. Of all the numerous organisms which are found in pyæmia and septicæmia the streptococcus is the most frequent, although in what was clinically known as a "pyæmia" other micro-organisms have been isolated, notably staphylococcus pyogenes aureus, bacillus coli communis, gonococcus, and actinomyces. Thus, at the present time it must be accepted that "pyæmia" is a collective name for metastatic suppurative processes of differing origins (Virchow). The nomenclature is palpably defective. To be strictly accurate one should speak of a streptococcic pyæmia, or staphylococcic pyæmia, or still better of a "metastatic strepto-mycosis," and for cases which have been called streptococcic septicæmia "non-metastatic general strepto-mycosis," reserving the term "septicæmia" for a class of cases caused by the entrance and local multiplication of *putrefactive* organisms within the body. In the case of large wounds the usual thing which leads to metastatic strepto-mycosis is phlebothrombosis of the vessels of the wound. The thrombi break down and fragments are carried into the blood stream as septic emboli, which in turn give rise to purulent deposits at the site of their impaction. Since the introduction of the Listerian treatment of wounds such cases are uncommon, yet they are not infrequently seen after streptococcic middle ear disease with sinus thrombosis. Cases in which pyæmia follows a slight wound are still more uncommon, having their etiological position midway between cases of phanerogenetic and cryptogenetic infections. In

the latter class of infection the cocci apparently enter the blood stream directly, giving rise to an endocarditis with secondary lesions in the spleen, kidneys, and liver, the part played by emboli seeming to be slight, as the resulting abscesses are usually small and miliary, although septic vegetations on the cardiac valves may cause typical embolic infarctions. In addition to the purulent deposits caused by the streptococcus pyogenes, putrefactive and gangrenous processes may be superadded—true septico-pyæmia.

Puerperal fever, puerperal pyæmia, and puerperal septicæmia.—In the great majority of cases of what is termed "puerperal fever" the cause is the infection of some part of the genital canal by the streptococcus pyogenes, but its action may be aided by other pyogenic cocci (staphylococci), and recent research has demonstrated that a puerperal fever may be set up by the gonococcus (Krönig[19]), bacillus coli communis (Maromrek,[20] Eisenhart,[21] Kleinknecht,[22] and others), the Talamon-Fränkel coccus (Czemetschka[23]), and a capsulated bacillus (Chiari[24]). The primary point of entry of the streptococcus may be in the vulva, vagina, or uterus, resulting in an inflammation and ending in necrosis of the tissue. The necrotic part sloughs and a "puerperal ulcer" remains. The further invasion of the system by the pyogenic organisms may take place by way of the lymph vessels or by the bloodvessels. Hence arise the two main forms of puerperal fever—the phlegmonous and the pyæmic. They have marked points of difference, yet the one may become the other, or both may be found coexisting. In phlegmonous puerperal fever the uterine mucous membrane is inflamed, the discharge has often a foul smell, and actual gangrene of the uterine wall may ensue; the lymphatics of the uterus are soon involved, the lymphangitis spreading to the loose connective tissue of the pelvis and to the broad ligaments, while later the lymphatics connecting the pelvis with the abdomen become similarly affected, peritonitis generally supervening. Pleurisy may follow, and if the progress of the disease is not arrested general infection sets in. The starting-point of pyæmic puerperal fever is usually a pyogenic metro-phlebitis at the site of the placental attachment. Thrombi are formed and sooner or later soften and break down; particles infected by chain-cocci are drifted off as emboli into the general circulation, and at the points of their arrest in the viscera metastatic abscesses are formed. A third form, bearing a strong resemblance to the rapidly fatal forms of non-metastatic general strepto-mycosis seen in rabbits after inoculation with highly virulent streptococci, may also be recognised. In cases of this class the macroscopic lesions are slight, although bacteriological methods demonstrate the fact that all the organs are teeming with specific cocci. In the primary genital lesion and in the various lymphangitides and metastatic foci chain-cocci were found by Waldeyer,[25] Orth,[26] Doleris,[27] and others. In the phlegmonous form it may be given as a general rule that the coccic distribution is limited to the parts inflamed, while in the pyæmic form they can be demonstrated in the blood at an early stage (Birch-Hirschfeld,[28] Hahn,[29] Ott,[30] and others). The severity of cases of puerperal fever seems to a large extent to depend upon the virulence of the cocci, and, as in erysipelas, the epidemic form is more severe than the sporadic. For the physician it is of extreme importance to determine if possible the source and nature of the infecting organisms. The researches of Döderlein,[31] Bumm, and others show that the uterine secretions of normal lying-in women are germ-free. In the vagina, however, various schizomycetes are present, and among them streptococci, but the latter are attenuated forms. The cause of this attenuation, according to Döderlein, is to be sought in the acid reactions of the secretions. To the already existing streptococci in the vagina may be due the strepto-mycoses occurring during pregnancy itself, but in the majority of cases the pathogenic streptococci are exogenous. Putrefactive organisms of themselves will not cause a puerperal pyæmia, as recently asserted by one of our most experienced gynæcologists. They may aid the streptococcus, the result being a combination of a pyogenic process with a putrid intoxication—septico-pyæmia, usually running an acute fatal course. In some cases the putrefactive organism isolated has been the proteus vulgaris of Hauser. The necrofactive action of the streptococcus probably aids the local development of the proteus. As a rule, however, puerperal fever is a pyogenic process caused by the streptococcus pyogenes only, and would, therefore, be better named "puerperal strepto-mycosis."

In a large number of diseases of the respiratory system streptococcus pyogenes plays a *rôle* of supreme importance. Claissé[32] has shown that it is responsible for many cases of bronchitis. In the lobular pneumonia following measles (Mosny,[33] Netter[34]), typhoid fever (Neumann[35]), scarlet fever (Babés[36]), and diphtheria (Prudden and Northrup[37]) the streptococcus is the organism almost exclusively met with. In the pathogenesis of certain cases of croupous pneumonia it is to be regarded as the primary cause (Finkler). The streptococcus described by Weichselbaum as the streptococcus pneumoniæ is, according to Mosny, identical with the streptococcus pyogenes. Harbitz[38] has recently described five cases of non-typically coursing croupous pneumonia, in four of which he found the streptococcus in pure culture. It is also a frequent associate of other specific organisms in lung diseases. In influenza it is of so frequent occurrence that it was described as the cause of the disease before Pfeiffer's classical researches (Finkler,[39] Ribbert,[40] Laveran,[41] Bouchard,[42] and others). As a rule, its association with the bacillus of Pfeiffer occurs in the more severe forms, and a fatal termination is not infrequent.

In cases of pulmonary tuberculosis the association of the streptococcus pyogenes with the bacillus of Koch is of enormous importance. It has been the subject of important researches by Cornet,[43] Petruschky,[44] Babes,[45] Spengler,[46] Pasquale,[47] Wunscheim,[48] and others. In twelve out of twenty cases Cornet demonstrated streptococci both during life and after death. In the hectic fever of phthisis the remitting temperature curve has been described as the "streptokken kurve." Although Petruschky has affirmed that streptococci from post-mortem phthisical material possess slight pathogenic attributes experimentally, still it is known that a general strepto-mycosis may follow (Canon[49]). Certainly the coccus is very frequently seen in the sputum of phthisical individuals, and Jakowski[50] has demonstrated it in the blood in the hectic fever of phthisis.

The conclusions of Spengler from a series of fifty cases carefully examined bacteriologically probably express the true state of affairs—viz., that in ordinary lung tuberculosis only a small percentage of the cases are uncomplicated. The majority are polymicrobic infections, the principal agents being tubercle bacilli and streptococci. The latter penetrate the parenchyma of the lung, generally setting up inflammation. As a rule, bronchiectases and vomica formation are associated with the presence of a large number of streptococci in the sputum.

In the etiology of diseases of the nervous system and its membranes the streptococcus pyogenes is important. While the diplococcus pneumoniæ is the most common cause of epidemic cerebro-spinal meningitis, a few cases are on record (in small epidemics) where streptococci have been found (Bonome,[51] Oebke,[52] &c.). The identity of these with the streptococcus pyogenes is, however, still a matter of doubt and requires extended study. Certainly sporadic cases of suppurative meningitis are often caused by the streptococcus pyogenes (Neumann and Schaeffer,[53] Netter.[54] and Beck[55]). The point of entry of the cocci in these cases is doubtful. Some of them may probably follow primary unrecognised lesions in the middle ear, antrum, and nasal cavities. The lymphatic connexions which have been demonstrated by Axel Key and Retzius to exist between the nasal mucous membrane and the subarachnoid lymph space afford a possible channel for the passage of the infecting organisms. In suppurative meningitis following influenza a suppuration in the region of the foramina cribrosa and the ethnoid cells was present in one case (personal observation). In Beck's case a streptococcic meningitis appeared to be set up by a primary tonsillar infection of similar origin. In a case of Landry's paralysis, which was a secondary complication of variola, Oettinger and Marinesco[56] found streptococci in the bloodvessels and also in the cells of the cord.

The cavity of the mouth is one of the chief regions for streptococcic lesions, monomicrobic and polymicrobic. The recent researches of Lemoine[57] have shown that the commonest cause of *all* the forms of non-diphtheritic angina is the streptococcus pyogenes, which can usually be isolated in pure culture from the deeper parts of the tonsil. The association of the streptococcus with the Klebs-Löffler bacillus is one of the best known and most completely studied. Apart from the buccal cavity the streptococcus was not believed to be a pathogenic agent in the alimentary tract except in the case of typhoid, where its association with Eberth's bacillus gives to the cases a high degree of severity (Vincent[58]). Recently, however, several writers (Tavel, Eguet, and de Cérenville[59]) have described a very severe form of streptococcic enteritis, in which some of the cases presented acute choleraic symptoms with final septico-pyæmia, while on post-mortem examination enormous numbers of streptococci were found in the stomach and along the length of the intestine. In certain cases of icterus Sabrazes and Mongour[60] isolated by puncture streptococci from the liver during life. They think that in such cases the streptococci wander into the bile ducts from the duodenum where they are normally found (Gessner). Buhl has described typical acute yellow atrophy of the liver following severe general strepto-mycosis, and more recently Babés[61] has examined similar cases of acute hæmorrhagic strepto-mycosis accompanied by complete degeneration of the liver. In three out of four cases a gangrenous or putrid tonsillitis seemed to have been the starting point of the hæmorrhagic septicæmia. In the fourth case a streptococcic infection of the intestinal mucous membrane seems to have been the starting point.

The streptococcus pyogenes has frequently been found in suppurative pleuritis and in peritonitis. It has been isolated from cases of acute osteomyelitis (Fischer and Levy[62]). Netter[63] and Raymond[64] have found it a cause of so-called "pseudo-rheumatic fever," which in many cases is really a cryptogenetic strepto-mycosis. Widal affirms that it is a frequent cause of phlegmasia alba dolens. In cases of elephantiasis nostras it has been isolated in pure culture by Achalme and Sabourand.[65] Unna[66] has described a special form of acute exanthem under the term "phlytænosis streptogenes." In certain cases of primary acute nephritis it has been isolated (Mannaberg[67]). In scarlet fever it is so frequently found that some have maintained it to be the cause of the disease, but most regard it merely as an associate. It has been found in the various forms of angina, bronchopneumonia, phlegmon, nephritis, otitis, pyæmia, complicating this disease.

In variola the suppurative stage of the eruption is caused by the secondary introduction of pyrogenic cocci—amongst them the streptococcus pyogenes. A metastatic strepto-mycosis in variola is not uncommon (Vagedes[68]). Marinesco[69] has also found streptococci in the central canal of the cord in a person dead from variola. To continue, however, the enumeration of the diseases in which the streptococcus pyogenes plays a part would be futile. Enough has been written to point out the vast field which is opened up for specific serumtherapy. One word, however, remains to be added on the transmission of streptococcic disease from animals to man. As yet observations are few. Holst[70] has recently recorded an account of four epidemics of acute gastro-enteritis, probably caused by drinking milk from cows suffering from contagious mammitis, a disease also caused by a streptococcus form (Nocard and Mollereau).

In a future communication I propose to deal with the question of the immunisation of large animals against streptococcic infection, work which has been carried on for many months by Dr. Ruffer and myself in conjunction with Mr. W. Robertson, M.R.C.V.S., of the British Institute of Preventive Medicine.

VITALITY.

By LIONEL S. BEALE, M.B., F.R.C.P. Lond., F.R.S.,
PHYSICIAN TO KING'S COLLEGE HOSPITAL; JOINT PROFESSOR OF MEDICINE IN, AND FELLOW OF, KING'S COLLEGE, LONDON.

II. Evidences of Vitality.[1]

Every living organism and every particle of living matter, however minute, affords evidence of the continual operation during its life of an active power or agency—vitality; and all the tissues of living organisms have been formed from matter which previously to formation had been under the direct influence of this vital power. There is not a piece of solid bone or tooth or shell, whether taken from an organism recently alive or from a fossil which lived thousands or hundreds of thousands of years ago, that does not bear evidence of its origin from living matter as distinct as that afforded by a piece of hair or horn or nail or feather formed within a few months and removed but yesterday from a living organism. In short, the matter of these and other tissues was once in the living state, and if only the microscopical structure, or even a cast of it, should have escaped destruction by violence or by chemical disintegration, it can generally be identified as having formed part of a living organism. In some instances special characteristics are so marked that the structure or its impression can be recognised as having belonged to a particular

[1] No. I. was published in THE LANCET of Feb. 22nd.

Digitized by Google

species. Such results of vital action cannot easily be mistaken for products of mechanical or chemical action. The minute silicious remains of recent and fossil diatoms and the spicules of sponges are as clearly the result of past vital action as is a piece of fresh muscle or nerve.

The vital movements of the actual structureless living matter of an organism, the growth of living matter, its powers of analysis and synthesis, or of preparation for the last, and its derivation from pre-existing living matter, proclaim the existence of a power widely different from any mechanical, chemical, or other properties of non-living substances; and unless we admit the operation of vitality it will be found as impossible to account for the characteristics of the lowest, simplest organism, though it has been held to be nearly related to the inorganic as to explain the formation, structure, and action of the most complex organ of man himself. The powers or properties and the action of the simplest bacterium afford evidence of the operation of vitality as convincing as that afforded by the living matter concerned in the highest mental operations of man. Although it has been declared again and again that living things are machines, not one of the many advocates of mechanical doctrines of life has been able to point to one machine that has *grown* or to a living organism that, like every machine, has been made in separate pieces, afterwards put together, and then set in motion, to say nothing of repairing itself while working without intermission.

All attempts to prove, and they have been many, that this vitality—this special endowment of all life—is a kind of force or mode of energy have failed. Life cannot be included among forces and forms of energy. Neither can it be shown to be correlated with any of these. Vitality is not a mere name applied to certain phenomena, the true nature of which is to be elucidated in the time to come; nor is it reasonable to regard vitality as one of a number of unsolved and possibly insoluble mysteries of the universe, and therefore not a subject for scientific investigation. Vitality is certainly capable of being more accurately defined, and though it may remain a mystery as regards its origin the study of the results of its action and the consequences and effects of its operation upon material particles will almost certainly lead to more correct views concerning its nature. Vitality exhibits nothing in common with any so-called properties or activities in nature. Vitality stands absolutely alone, but in its action through nature, in the case of the very lowest as well as the highest organisms, there is much in common. It is always in very close relation with the matter it influences and it cannot act upon particles of matter even at a very slight distance from the seat of its activity, and it acts in a way in which no other force or power in nature is known to act upon matter. No vital action can be imitated, and the vitality of the lowest forms of life is as far removed from any known physical or chemical change as the highest and most complex form of vital action. Living and non-living actions belong to different categories and have nothing in common. The growth and multiplication of particles of living matter may be studied in the lowest organisms or in an elementary part or cell of any of the higher animals or man himself, and these vital forms of increase and multiplication are distinct from every kind of aggregation, coalescence, or process akin to crystallisation or deposition, of which as yet we have knowledge or experience.

But if, as I have endeavoured to show, a general survey of various organisms in widely separated classes of living nature furnishes convincing evidence of the constant operation in all living things of a marvellous and special power not to be isolated, tested, analysed, or transformed, to which the vital phenomena of each form of living matter must be referred, the more minute examination of any of the constituent elementary parts or cells of any one organism brings us, as it were, very much nearer to the actual seat of operation of this wonderful agency, and we are even enabled to realise to some extent the character of the changes effected in the non-living pabulum when it comes under the influence of matter already living. We can distinguish the living matter from the surrounding material, be it cell wall, tissue, or fluid, in which no vital changes occur. By the use of very high magnifying powers and successful illumination we may have under actual observation the minute particles of matter in which vital changes are actually proceeding. If, however, as seems very possible, we should be able to double or treble the highest magnifying powers now at our disposal, and if in many ways we may render still more perfect our methods of examination, we should still be so very far from discerning the actual particles of matter undergoing atomic rearrangement by the direct influence of vitality that we should not be able to add to our knowledge. Nor is there at present any hope of our being able to form an accurate idea of the precise manner in which the changes in position of the atoms is accomplished. Here, then, is the mystery, the solution of which must, it is to be feared, be put off till the time when new and important discoveries shall have been made concerning the analytical and synthetical operations proceeding in the living matter.

Let us look at the problem from another point of view—the minute structure and formation of any tissue or organ—and let us try whether we can suggest anything in the non-living world or anything that has been designed and made to act by man with which the life-made structures will compare. Think also of the means of repairing, and even of renewing, some structures during life without any disturbance of the action of the greater part of the adjacent tissue. Where in non-life can we find anything parallel? Every particle of the tissue of a living organism was once in the state of living matter before it manifested any tissue characters whatever. The arrangement of its component elements, the properties it exhibits, its internal structure, are all due to the changes brought about when the matter of which it consists was in the living state. Is not this, again, evidence of the operation of a peculiar power which acts in every living organism in every department of nature? Think over the characteristics and form of various organisms and their adaptation to the conditions under which they are placed, and the fact of the transmission of the characteristic features, even in minute detail, through countless generations—in some cases without modification, in others with limited changes, while in some, many centuries may have passed without all the possible changes in the characters of a species being exhausted. And yet, notwithstanding striking departures and in many different directions from the primitive form, each divergent variety still retains the wonderful capacity of reverting to the original type in a few generations. Such facts are, it need scarcely be said, peculiar to the living world and absolutely due to the operation of vitality.

As regards certain vital phenomena which can be studied only by the use of very high magnifying powers, I shall endeavour to show how far our real knowledge justifies us in looking forward at this time, and I shall try to indicate precisely where the mysterious and so far inexplicable vital changes are effected. The mysteries connected with physiological and pathological phenomena I hope to reduce to a small number, to indicate and limit the seat of operation of the real mystery of life and discuss in what the mystery consists. Some vital phenomena can now be actually recognised and subjected to investigation—indeed, I feel that we are approaching very near to some knowledge of the actual particles of matter which undergo vital change, that is, to a point beyond which it has not been possible to carry investigation—in fact, to the region of mystery common to every form of life that is, that has been, and that is to be. It is in this region that wonderful chemical changes far indeed removed from any that can be produced under laboratory conditions take place. By what means the changes in question are effected by vitality is at present unknown and may be unknowable. This part of my subject I shall venture to discuss when the change of the non-living nutrient matter which undoubtedly passes into the very substance of the living matter comes under consideration.

Living matter is also directly concerned in the production of the various secretions of glandular organs. The characteristic substances present in the secretion are not merely *separated* from the blood, but are actually *formed* by the so-called secreting cells. The living matter of each cell or elementary part takes up nutrient materials for the most part in solution and causes certain of these to live. The elements of the matter in the living state are rearranged under the influence of the vital power and caused to take up new relations in respect to one another, so that when the living particles pass into the non-living state the substances peculiar to the secretion are formed. In some secreting elementary parts or cells it is even possible to see some of the less soluble substances that have been formed, in the matter of which the outer part of the cell consists. For example, embedded in the soft material of the liver elementary part, oil globules, biliary matters, and other substances may

Digitized by Google

be detected on microscopical examination, while glycogen, urea, and some other substances may be shown to be present by chemical analysis. Not only so, but the quantity and the relative proportions of the respective constituents may be caused to vary by alterations in the food constituents. This is a matter of great interest to us, for when an organ is deranged by injudicious feeding we can in some cases, by a change in the diet for a sufficient period, and by the help of certain medicines, promote an increase or reduction in the amount of the constituents of which there may have been deficiency or excess, or we can encourage the removal of some substances from the organism and promote the retention of others. The different classes of substances formed in varying proportions such as proteids, fatty matters, salts, and carbohydrates, also vary according to the conditions under which the organism for the time lives. In some cases an organism may be caused to produce and to accumulate fat to an enormous extent, and it may more than double in weight within a short time, or, on the other hand, the animal may be kept lean and highly active—in fact, its muscular and nerve power may be increased and thus it may be made to perform work which would have been impossible if a large proportion of adipose tissue existed. But neither of these processes—the formation of fat or its removal—could be brought about in the absence of a special power operating in living things only, the increase of adipose tissue as well as its removal being effected by living matter. And we must bear in mind that the too rapid removal of the fat of adipose tissue by great changes in diet may endanger life.

Physiological and pathological phenomena include vital actions and depend upon vitality. They are not to be imitated or to be adeqately explained by physics or chemistry in the present state of knowledge. We must in all cases admit the operation of a power communicated by pre-existing living matter to non-living matter of a certain composition and in a certain condition. Thus has the earth been peopled by successive generations of countless living forms of the most different kinds, all of which and at every period of existence have been dependent upon vitality, being also subject to pathological changes and various forms of disease.

TWENTY-FIVE CONSECUTIVE CASES OF STRANGULATED HERNIA; ONE DEATH.[1]

BY W. THELWALL THOMAS, F.R.C.S. ENG.,

HONORARY ASSISTANT SURGEON TO THE ROYAL INFIRMARY, LIVERPOOL; DEMONSTRATOR OF SURGERY AND SURGICAL PATHOLOGY, UNIVERSITY COLLEGE, LIVERPOOL.

DURING the last few years it has fallen to my lot to operate on 25 cases of strangulated hernia, of which only 1 died as a direct result of the operation. To simplify this paper I have appended a table of the cases. Twelve occurred in men, and 13 in women. The ages varied from twenty-six to seventy-eight years, 6 being over sixty and 3 over seventy years. The period of strangulation varied from ten hours (cases Nos. 11 and 22) to five days (case No. 16). The bowel in 1 case (No. 16) was greenish and had a putrid smell, but retained its shiny appearance. The omentum was gangrenous in Case 20 and the fluid in the sac, of course, decomposed and was very offensive, although the bowel looked alive, and recovered. The bowel alone was present in 9 cases; the bowel with omentum was present in 12 cases; and the omentum alone was present in 2 cases. Omentum was removed in 11 cases; the portion removed varied from a "mere tag," in Case 18, to a pound, in Case 10. Omentum formed a complete sac, adherent universally to the peritoneum, in Case 24, an umbilical hernia, and contained a large loop of strangulated small bowel. In Case 14 there were 3 hæmorrhages in the omentum, one of which looked at first sight like a knuckle of intestine. In Case 15 there was diffuse cellulitis of the abdominal wall, with sloughing of the convexity of the sac; all the sloughs were cut away, and the tissues swabbed with pure carbolic acid (the bowel being protected) before dividing the constriction, so that neither putridity nor acid could enter the abdominal cavity. This was of course a very serious complication, but the woman recovered with a fæcal fistula. The bladder was present alongside a strangulated right inguinal hernia in Case 25, a very rare occurrence. Up to 1893 only 59 cases had occurred in surgical literature,[2] and Macready[3] had only been able to collect 36 cases.

Details of procedure.—Chloroform was used as an anæsthetic in every case, although in Case 10 only a few whiffs were given, the patient being deeply cyanosed from a very acute attack of bronchitis. His knees were strapped down and his hands held whilst the skin incision was rapidly made. He was by no means "under chloroform." The anæsthetic was laid aside and the remainder of the operation conducted with the man conscious, and he experienced no pain during the necessary manipulation of the sac, intestine, and the removal of a pound of omentum; but when the sutures were being passed through the skin his language was "frequent and painful and free." In Case 20, an old man aged seventy-six years, with chronic bronchitis and emphysema, was operated upon propped up in bed with four pillows. Mr. Caregan administered a few drops of chloroform; with my left elbow I kept the patient's knee down and held a dissecting forceps in my left hand, the knife being in the right. The operation was quickly completed; it necessitated the removal of two pieces of gangrenous omentum, the return of the bowel, the ligature of the sac, and the introduction of only one suture in the skin. Both these cases recovered without a bad symptom. In all the operations speed was particularly cultivated and I believe had much to do with the happy result.

Treatment of the contents of the sac.—Investigations have demonstrated the poisonous nature of the fluid found in the sac of strangulated hernia. I need only quote Nepveu and Garré,[4] who found bacteria, and these did not appear to bear any relation to time or degree of strangulation (putridity apparent to the sense of smell being no guide). Clado[5] inoculated animals with fluid from the sac of a strangulated hernia. The animals died, and the organisms were found in the blood, spleen, lungs, and the serous cavities. He considers death in strangulated hernia due to the introduction of organisms from the intestinal tract into the general circulation. This position is strengthened when we bear in mind that about 10 per cent. die when the strangulated hernia is reduced by taxis. Benno Schmidt[6] considers the field of operation in strangulated hernia already septic. Bearing in mind these and similar statements by many investigators, special attention was paid to disinfection of the sac contents as soon as opened and before any attempt at reduction. This was always carried out by freely washing the fluid away with hot 1 in 40 carbolic lotion, until every shred of lymph and blood-stained material was thoroughly removed from amongst the coil or coils of intestine and the interstices of the omentum when present. When it was decided to remove omentum a fresh portion was dragged down and this ligatured and divided, when the piece in the sac, being now deprived of its blood-supply, could be forcibly torn away, if adherent, without risk of hæmorrhage. This method materially aids rapidity of procedure.

Radical cure.—In the worst cases, and in the old people, Czerny's radical cure, simple ligature of the neck of the sac, was performed, Macewen's method being used in the younger patients and in those cases where urgency was not so imperative and a more certain radical cure indicated. Two cases (Nos. 4 and 17) had congenital inguinal sacs, and the portion cut off for a tunica vaginalis was closed with a continuous catgut suture.

Treatment of wound.—Silkworm gut sutures, double cyanide gauze under wood wool tissue, and a suitable bandage or binder were used. In only two were there wound complications—Case 15, where a fæcal fistula formed, and Case 25, where the wound suppurated, necessitating the reopening of the inguinal canal. This was due to contamination with ammoniacal urine from a hernia of the bladder, which complicated the case. It occurred in a man aged fifty-nine years, who was admitted into the infirmary for strangulated hernia, and operated upon at once (11.30 P.M.). He

TWENTY-FIVE CONSECUTIVE CASES OF STRANGULATED HERNIA.

No.	Age.	Sex.	Where operated, and date.	Doctor's case.	Variety of hernia.	Strangulated time.	Contents of sac.	Condition of bowel.	Details of operation.	Result.
1	58	M.	Ormskirk Workhouse, Dec. 19th, 1891.	Mr. Anderton.	Right scrotal.	2 days.	8 inches of bowel and omentum.	Dark purple.	4 oz. of omentum removed; Ball's radical cure.	Cured.
2	30	M.	Liverpool Royal Infirmary, Nov. 12th, 1892.	—	Right inguinal.	?	Loop of the bowel.	Dark purple.	Ligature of the neck of the sac.	Do.
3	76	M.	Wavertree, Nov. 26th, 1892.	Dr. O'Hagan.	Left scrotal.	2 days.	4 inches of bowel, omentum congested and hæmorrhagic, blood-stained serum 2 oz.	Dark purple.	The ring was incised; neck of the sac ligatured.	Died.
4	26	M.	Liverpool Royal Infirmary, Jan. 8th, 1893.	—	Right scrotal.	19 hours.	6 inches bowel; congenital sac strangulation by external ring; bowel in canal normal.	Dark purple.	The sac was divided; the tunica vaginalis was sutured for testicle; the neck was ligatured.	Cured.
5	69	F.	Private house, June 5th, 1893, 12.30 A.M.	Mr. Edwards, Anfield.	Left femoral.	3 days.	"Large knuckle" (no omentum).	Dark purple.	Gimbernat's ligament was incised and the neck of the sac ligatured.	Do.
6	36	M.	Liverpool Royal Infirmary, June 25th, 1893.	—	Right inguinal.	3 days.	About 4 inches of bowel.	Dark purple.	The sac was ligatured (funicular process).	Do.
7	61	F.	Liverpool Royal Infirmary, July 28th, 1893.	—	Left femoral.	Obstructed, going on to strangulation, 1 week.	Knuckle of bowel, mass of omentum.	Dark purple.	Gimbernat's ligament was nicked. The neck of the sac was ligatured and omentum removed.	Do.
8	78	F.	Private house, Oct. 20th, 1893.	Mr. Laing, Burscough.	Left femoral.	2 days.	Knuckle of bowel, flakes of lymph.	Dark purple.	Reduced without incision of the neck; ligature of the sac.	Do.
9	30	F.	Liverpool Royal Infirmary, Oct. 28th, 1893.	—	Left femoral.	—	5 inches bowel and adherent omentum.	Dark purple.	Removal of omentum.	Do.
10	43	M.	Liverpool Royal Infirmary, April 14th, 1894.	—	Umbilical.	2 days.	4 inches small gut and omentum.	Dark purple.	1 lb. of omentum removed; neck of sac tied.	Do.
11	34	M.	Liverpool Royal Infirmary, April 23rd, 1894.	—	Right inguinal.	10 hours.	—	—	—	Do.
12	58	F.	Liverpool Royal Infirmary, April 12th, 1894.	—	Left femoral.	24 hours.	2½ inches of intestine and omentum.	Dark purple.	Removal of omentum; ligature of the neck.	Do.
13	39	M.	Liverpool Royal Infirmary, April 29th, 1894.	Mr. Dunn.	Right inguinal.	12 hours.	3 inches of intestine.	Dark purple.	Macewen's radical cure.	Do.
14	52	F.	Liverpool Royal Infirmary, May 6th, 1894.	—	Left femoral.	2 days.	Omentum only, with 3 blood cysts (simulated bowel).	—	3¾ oz. of omentum removed; adherent around two-thirds of the orifice.	Do.
15	53	F.	Liverpool Royal Infirmary, Oct. 8th, 1894.	—	Umbilical.	3 days.	Loop of large bowel, omentum.	Odorous but shiny, omentum sloughy.	Portion of the sac removed; sloughy cellular tissue of abdomen suppurating, constriction divided, omentum removed, sac tied.	Do.
16	52	F.	Liverpool Royal Infirmary, Dec. 3rd, 1894.	—	Umbilical.	5 days.	Loop of bowel and omentum.	Dark purple.	Operation rapidly performed; bowel pushed back.	Died same night.
17	55	M.	Liverpool Royal Infirmary, Dec. 9th, 1894.	—	Left inguinal.	12 hours.	Congenital sac, large loop of bowel.	Dark purple.	Tunica vaginalis made and sutured for testicle. Macewen's radical cure.	Cured.
18	45	F.	Liverpool Royal Infirmary, Jan. 14th, 1895.	Dr. McGibbon.	Left inguinal.	2 days.	Omentum only.	—	Large amount of inflamed extra-peritoneal fat removed; sac treated *à la* Macewen; tag of omentum removed.	Do.
19	50	F.	Private House, March 8th, 1895.	Mr. Laing, Burscough.	Right inguinal.	12 hours.	Knuckle of bowel and tag of omentum adherent to sac.	Dark claret.	Omentum removed; neck of sac ligatured.	Do.
20	76	M.	Private House, June 16th, 1895.	Mr. Caregan, Ormskirk.	Left inguinal.	2 days.	Knuckle of bowel; sloughy omentum; stinking blood-stained serum.	Dark purple, shiny.	Omentum was removed; the sac was well purified; ligature around neck; one suture in skin.	Do.
21	64	F.	Liverpool Royal Infirmary, June 30th, 1895.	Dr. Samuels.	Right femoral and left femoral.	Left; 24 hours.	Knuckle of bowel.	Dark purple.	Gimbernat's ligament was nicked; Macewen's radical cure; right hernia chiefly extra-peritoneal fat; nothing in sac.	Do.
22	46	F.	Liverpool Royal Infirmary, Sept., 1895.	Dr. Mercer, Ditton.	Right femoral.	10 hours.	3 inches of bowel adherent to omentum, bloodstained fluid.	Dark purple.	Gimbernat's ligament was nicked: Macewen's radical cure.	Do.
23	58	M.	Liverpool Royal Infirmary, Sept. 26th, 1895.	Dr. Blackledge, Tuebrook.	Right inguinal.	2 days.	2 loops of about 8 inches each, 1 loop twisted and strangulated.	Dark purple.	Macewen's radical cure.	Do.

TWENTY-FIVE CONSECUTIVE CASES OF STRANGULATED HERNIA—*Continued.*

No.	Age.	Sex.	Where operated, and date.	Doctor's case.	Variety of hernia.	Strangulated time.	Contents of sac.	Condition of bowel.	Details of operation.	Result.
24	38	F.	Liverpool Royal Infirmary, Sept. 29th, 1895.	—	Umbilical.	25 hours.	Large loop of small bowel with omental sac.	Dark purple.	Omentum was dissected away off sac; ligatured vessel by vessel; the sac was ligatured.	Cured.
25	59	M.	Liverpool Royal Infirmary, Oct. 21st, 1895.	Mr. Dudgeon.	Right inguinal through internal ring.	24 hours.	Loop of bowel; large hernia of bladder through back wall of inguinal canal into scrotum, adherent to sac of hernia of bowel.	Dark purple.	Macewen's radical cure on sac of hernia; the bladder was replaced.	Do.

REMARKS.—Case 1: Slight recurrence of the hernia 6 months afterwards. The patient was a chronic bronchitic, and uses a light truss now (1895). Case 2: The notes of this case are mislaid. Case 3: All the symptoms were relieved, and the patient took food. He had an enlarged prostate, cystitis, and incontinence, also ammoniacal urine requiring frequent catheterising. He died on the 6th day from coma (uræmia). The wound was clean. Case 9: Slight recurrence of hernia in April, 1894; controlled by light truss. Case 10: The man was deeply cyanotic from bronchitis. Only a smell of chloroform was given to dull sensation for the skin incision. He was fully awake and talking with us during the remainder of the operation. Case 11: The notes of this case are mislaid. Case 12: 3 weeks after operation suffered from attacks of colic, which yielded to starvation and opium. Case 14: Omental hernia with marked strangulation symptoms. Case 15: Recovered with fæcal fistula; 6 months later after failure of attempt to remove the "spur" Murphy's button was used, but the patient died from shock of the operation the same night. Case 18: Patient had feculent vomiting for 24 hours before admission; her pulse could hardly be felt the collapse was so marked, but it was considered advisable to attempt the operation. Case 17: Troublesome bronchitis. Case 18: Although no bowel was found during the operation, there had been absolute constipation and incessant vomiting for the 2 days. Case 20: The wound was left practically open. The patient was so ill from bronchitis that he could not lie down, he was in a semi-sitting position and only partially placed under chloroform. Six months later he died suddenly while out walking. Case 21: Left hernia only strangulated, but the existence of an irreducible lump on the right side necessitated its exploration. Case 22: On the third day there was some distension of the abdomen and tenderness which yielded to saline purge. Case 25: The bladder hernia was as large as a fist and surrounded by a layer of cellular tissue which formed a sac for it and which was ligatured in a bunch after reducing the bladder which had been emptied through a puncture; this puncture was closed by two rows of Lembert sutures.

In the above table 25 cases of strangulated hernia are given:—In Nos. 14 and 18 omentum only was found in the sac. Males: Inguinal right, 8; inguinal left, 3; and umbilical, 1. Females: Femoral left, 7; femoral right 2; inguinal right, 1; inguinal left, 1; and umbilical, 3. The ages of the males were 26, 30, 34, 36, 39, 43, 55, 58, 58, 59, 76, and 76 respectively, and those of the females 30, 38, 45, 46, 50, 52, 52, 53, 58, 61, 64, 69, and 78 respectively. There were two deaths (one directly after operation). The first was from cystitis, nephritis, and coma on the sixth day; he had been troubled with enlarged prostate for years; the bowel symptoms had been entirely relieved and the wound was healthy; this patient was a male aged 76 years (No. 3). The other was from collapse; the patient was in such a desperate condition that allowing her to die unrelieved was thought of; this patient was a female aged 52 years (No. 16). No. 15, a female, died six months afterwards from an attempt to repair a fæcal fistula.

was suffering from severe vomiting and pain, there being an irreducible swelling in the right groin and scrotum. On exposing the swelling it was found to consist of two parts: (1) a smaller, evidently escaping through the internal abdominal ring; this was opened and found to contain a knuckle of acutely nipped bowel, which was reduced and the sac treated *à la* Macewen; and (2) a larger, the size of a man's fist, which occupied the scrotum and the lower half of the canal; it evidently contained fluid; this was explored by making a tiny puncture, when out shot ammoniacal urine. It was therefore apparent that a portion of the urinary bladder had herniated. The edges of the puncture were at once clamped, a catheter passed per urethram, and the bladder and this pouch emptied. There was now seen a thin sheet of fibrous tissue stretched over the bladder hernia which was continuous with the back wall of the inguinal canal. It was dissected up and a finger passed between it and the bladder wall into the abdominal cavity and pelvis to separate tissues and prepare a place for it. This portion of bladder had no peritoneum over it and had escaped through the usual place of a direct inguinal hernia, quite three-quarters of an inch to the inner side of the internal abdominal ring. The sides of the puncture were closed by two rows of Lembert sutures, and after some manipulation the portion of bladder returned, the fibrous sac covering which was ligatured flush with the posterior wall of the inguinal canal. The wound suppurated as before mentioned and a slough formed, which was treated by rubbing with pure carbolic acid; after this the case ran an uninterrupted course.

Treatment of cases after operation.—After the first 2 cases morphia (or opium) was not allowed. This drug, although useful for relieving pain, acts directly on the intestinal wall, paralysing it, and thus preventing the bowel acting and relieving itself of flatus and "banked-up" contents. The routine administration of opium appears to rest on the assumption that the loop of bowel after return becomes inflamed. This is of course pure theory. Acting on the idea that if the bowel is fit to return it may be left absolutely to nature unhampered by any "paralyser," I have had no reason to regret it. In only one case (No. 22) did the patient complain of pain, which came on the third day, accompanied by distension and tenderness of the abdomen. This yielded at once to the action of a smart saline purge. Complications that may arise, such as peritonitis, enteritis, and persistence of strangulation, will be materially masked by opium, which eases pain, prevents diarrhœa and vomiting, and causes distension of the abdomen.

Diet.—For the first twenty-four hours sips of warm water only, ice being prohibited, for patients and nurses say that enough ice cannot be given to quench thirst; this is probably due to the dryness and hardness of the tongue produced by the abstraction of heat to melt the ice. If flatus be not passed by the end of this time the same starvation is indulged in until it does. After the passage of flatus half a pint of beef tea is granted during the next twenty-four hours; then, if all goes well, half a pint of milk is added the next day, increased by half a pint daily until two pints of milk and half a pint of beef-tea are reached, generally by the sixth or seventh day. The patients are kept on this until the bowels act. If by the ninth or tenth day no action of the bowels has taken place a dose of compound liquorice powder is given (sometimes an enema). The diet is now increased by the addition of fish, then beef tea, and, some of the milk being discontinued, chicken and a chop on successive days, and generally, unless any contra-indication, common diet by the end of the second week. The cases that recovered were all kept in bed for six weeks to allow of a firm cicatrix forming. In some of the older patients, particularly when much collapsed, a teaspoonful of brandy in a little warm water was given every hour for the first day, and continued if considered necessary in modified doses.

Results.—One patient died the night of the operation, and Case 16 from collapse. She had a large strangulated umbilical hernia, and was so reduced from fæcal vomiting that her pulse was hardly perceptible at the wrist; still, it was not considered right to allow an individual to die with bowel unrelieved. The operation lasted only a few minutes; there was no attempt at radical cure, merely two sutures passed through the skin and sac to close the aperture. Case 3, a man aged seventy-six years, died on the sixth day from coma gradually coming on from kidney mischief. He had enlarged prostate and cystitis with ammoniacal urine, and needed frequent catheterising. The bowel symptoms were all relieved. He was partaking freely of milk. The wound was healthy. With the usual leniency accorded to operators, this death not being counted, we can, I think, fairly place the mortality as 1 out of 25 cases—fortunately a very low figure when it is remembered that 6 were over sixty years of age (3 over

Digitized by Google

seventy years). I conclude with the belief that the prompt recognition of the condition and early operation, without the old-fashioned savage attempts at taxis (10 of the cases were operated upon within twenty-four hours), had much to do with the low mortality. When the operation is undertaken, rapidity, thorough antiseptic cleansing of the sac contents, no undue delay over so-called radical cure, and judicious starvation without opium can be relied upon to keep the deaths down to a small percentage.

Liverpool.

VENTRO-HYSTEROPEXY.

BY J. O'CONNOR, M.A., M.D., B.CH., T.C. DUB.
SENIOR MEDICAL OFFICER, BRITISH HOSPITAL, BUENOS AYRES.

DURING the past twelve months I have performed abdominal fixation of the uterus for prolapse eight times, and I wish to bring more fully under the notice of the profession the ease and certainty with which this operation may be executed, also the advantages of fibro-serous approximation, so ably advocated by Mr. Greig Smith. Quite recently I had an opportunity of realising the danger in anyone attempting to fix the uterus to the anterior parietes without opening the abdominal cavity. I particularly refer to a method of intra-uterine ventro-fixation recommended by Mr. Shober. On opening the peritoneal cavity, the omentum covered anteriorly the lower abdominal viscera in all directions, notwithstanding the fact that my two-inch incision extended to within half an inch of the pubes. If I had attempted to fix the uterus by a needle passed through the womb without opening the peritoneum, I certainly would have included the omentum; therefore with this experience—and I have seen the same in other cases—I have strong objections to working in the dark. In each of the eight cases there has not been the slightest post-operative complication; all united by first intention, in no instance did the temperature exceed 100° F., and no recurrence of the trouble has been reported, and, although I never order an abdominal belt to be worn afterwards, no ventral hernia has occurred. To my mind the latter mishap is due to deficient care in suturing the parietal wound. Of course a short period only has elapsed, therefore these latter observations can only be tentative. In a way I feel thankful that I have not as yet been afforded the opportunity of examining the class of adhesion that takes place, nor have any of my patients, so far as I know, tested the same by becoming pregnant. As some of them are young doubtless the test will be applied.

The operation is carried out as follows: The patient, having been "acclimatised" to hospital life for a fortnight, during which time sundry repairs are undertaken—curetting the endometrium, excision of the cervix, and colpo-perineorraphy, the bowels, if necessary, being well cleared out with repeated doses of magnesium sulphate—the day before the operation the pubic hair is shaved off and the skin of the abdomen scrubbed with soda, soap, and hot water, then washed with turpentine, and a large piece of lint soaked in a 1 in 500 solution of corrosive sublimate applied and fixed on for the night by antiseptic wool and a bandage. On the morning of the operation a large soap and water enema is given, and immediately before the patient is brought into the operating-room the urine is drawn off. The patient having been chloroformed the night's dressing is removed and the skin all round the field of operation is again scrubbed with a sponge soaked in turpentine and lastly thoroughly washed with Watson Cheyne's strong solution:—1. An incision two inches in length is made in the median line and extending to within half an inch of the pubes. All bleeding must be stopped before the peritoneum is picked up with a pair of dissecting forceps and opened; a few pressure forceps are attached to the cut edges of the peritoneum—these help greatly in after manipulations. 2. The left index-finger is passed down below the intestines and omentum to the uterus, with palmar surface, hooking the former upwards. With the tip of the finger steadied on the womb I pass down a Muzeux forceps on the dorsal aspect of the finger, seize the uterus, and pull it up to the wound. 3. An assistant now takes hold of the forceps and the presenting surface is scarified with the point of a scalpel; some trifling oozing takes place, which is easily arrested by sponge pressure. 4. At the lower angle of the wound a curved needle threaded with silk is passed from without inwards through the rectus muscle and transversalis fascia. The peritoneum being retracted by pressure forceps (previously applied) the needle is then passed for at least a quarter of an inch in depth into the uterus and made to emerge about half an inch from the point of entry. The peritoneum on the opposite side is next held back while the needle is passed from within outwards through the transversalis fascia and rectus muscle. In this manner three sutures at intervals of a third of an inch are inserted. Any bleeding from the needle punctures is arrested by sponge pressure. 5. The peritoneum is again held back on each side and these sutures are tied firmly and the ends cut off. (Care must be taken not to tie too tightly lest the silk sutures should cut through the uterus; firm approximation is all that is necessary.) In this manner the serous covering of the uterus is brought into intimate connexion with the transversalis fascia and recti muscles for half an inch in width and one inch in length. 6. Before closing the upper inch of the wound it is desirable to pass a small sponge held by torsion forceps into the peritoneal cavity in order to remove any blood or clot that may be present. The peritoneum is next closed by a continuous fine silk suture. It is well to pass the first stitch through the peritoneum on the side next the operator, then through the uterus, and, lastly, through the peritoneum on the opposite side. In this way the peritoneum is brought into accurate apposition with the serous coat of the uterus and prevents a subsequent site for ventral hernia. The recti muscles in the upper portion of the wound are then brought together by another continuous fine silk suture and the skin wound closed in the same manner. Iodoform gauze is applied. The first dressing is removed on the eighth day and the suture on the twelfth day. The patient is allowed out of bed on the fourteenth day.

There is one essential in the closure of this or any abdominal wound, and that is that no pocket must be left for the accumulation of serum or blood, for where these factors are thither staphylococci and other micro-organisms gather together—nay, more, thrive.

Buenos Ayres.

A CASE OF AXIAL ROTATION OF THE TESTIS.

BY ALFRED SHEEN, M.D. ST. AND.,
SENIOR SURGEON TO THE CARDIFF INFIRMARY.

A YOUTH aged eighteen years jumped over a hedge after a tennis-ball on July 5th, 1895, but felt no ill-effect at the time. On the 6th at 3 A.M. he awoke with severe pain and swelling in the testicle, it being all right when he went to bed. I saw him on the 9th in consultation, when the testicle was found to be considerably enlarged and somewhat tender. The temperature was normal although it had been up to 103° F. I advised immediate incision into the tunica vaginalis to relieve tension, and this was done at the Private Hospital at Cardiff on the 11th. On operation I found a dark-red mass like blood-clot, but not removable, and the testicle was swollen to the size of a small orange, globular in shape. All antiseptic precautions were carried out. The case pursued an aseptic course, the temperature being normal throughout. The stitches, however, gave way and a hernia of the testis resulted; there was no pain. The dead tissue was dry and was cut away with scissors. There was no sensation, common or testicular. It was obvious that the testicle was useless and it was removed on Aug. 9th; on the 20th the wound was dressed for the first time and the stitches were removed, the parts being nearly healed. The patient got up for a time day by day, was out for the first time on the 28th, and went home to London about the middle of September.

The specimen was sent up to the Clinical Research Association and they returned the following report:—"The specimen is an example of that rare condition described as *torsion of the testis*. The substance of the body of the testicle is healthy in itself; there are no signs of chronic inflammation, syphilis, or tubercle. Section of the epididymis shows an abundant extravasation of blood into its tissue, but there is no other lesion. This hæmorrhagic infiltration is due to twisting of the spermatic cord and

Digitized by Google

vessels (the result of injury) and gives rise to acute swelling and pain so that the cases have been mistaken for herniæ."

There was no question of hernia in this case. My diagnosis was hæmorrhagic orchitis. I had never seen a case of axial rotation, and that possibility did not present itself to my mind. Had the condition been recognised when first seen the cord might perhaps have been untwisted, as was successfully done in a case which is recorded by Mr. G. Nash.[1] A year or two ago Mr. Edmund Owen read a paper dealing with this subject. At a meeting of the Medical Society of London[2] he brought together references to fourteen cases which have been recognised during the past few years, and said that, as a rule, "it is only the unhappy possessor of an undescended testicle that gets into this very peculiar kind of trouble. It is almost as if nature herself, disappointed with her imperfect work, was anxious to cast it down a Tarpeian rock." Mr. Bryant, in reporting a case, surmises that certain cases of atrophied testicle have been examples of axial rotation, the nature of which has been originally overlooked. Twisting the cord in the lower animals is the French method of producing atrophy of the testes and sterility.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

GUY'S HOSPITAL.

A CASE OF MALIGNANT STRICTURE OF THE ŒSOPHAGUS; PERFORATION OF THE AORTA; DEATH FROM HÆMORRHAGE.

(Under the care of Dr. FREDERICK TAYLOR.)

IT is, happily, rare to find a carcinomatous ulceration of the œsophagus perforating the walls of an artery of large size; it is still more rare to find it perforating the aorta. In the references given by Dr. Taylor in his paper in the Guy's Hospital Reports the investigations of Altmann in perforation of the thoracic aorta from the œsophagus are detailed. The comparative rarity of the occurrence is shown, as it happened only four times in 6886 cases, a percentage of 0·058. In 38 instances death was due to hæmorrhage, in only 12 of these was the wall of the artery invaded by cancerous growth and the aorta was involved in only 4. It is not possible to say whether epithelioma is more likely to penetrate than other forms of growth or not, as the microscopic examination is not given in every instance. We have published in our columns[3] the notes of a case of perforation in a female lunatic where there were no symptoms of the presence of a growth manifested until the vomiting of about two ounces of blood. Afterwards the patient swallowed the blood and large quantities were passed per anum. The fatal ending does not seem in any case to have been induced by the passing of bougies or tubes. For the notes of the case we are indebted to Dr. L. A. Parry, house physician.

A man aged fifty-two years was admitted into Guy's Hospital under Dr. Taylor on Feb. 20th, 1895, for difficulty in swallowing. His family and previous history have no bearing on the case. His present illness dated from November, 1894—that is, about four months—and commenced with dull, aching pain in the lumbar and interscapular regions and frequent attacks of heartburn. In December, 1894, he began to have difficulty in swallowing, at first solids, then liquids; the food he got down into his œsophagus he quickly regurgitated; the dysphagia rapidly became worse, he lost a great deal of flesh, and he was admitted into the hospital on Feb 20th. He was then unable to swallow any solid food, and liquids only with effort. A medium-sized bougie met with definite obstruction thirteen inches from the teeth (seven inches down the œsophagus), but a small one was passed through the stricture right into the stomach. It was felt to hitch half way, and it was therefore thought that a pouch was present into which it had slipped. The patient was fed daily by means of a tube and on March 22nd an attempt was made to pass a Symonds's short tube. However, this could not be accomplished, and Mr. Symonds, thinking the cause of failure was probably due to the stricture being sinuous, suggested passing an ordinary feeding-tube and allowing that to remain *in situ* for thirty-six hours, thus hoping to straighten the stricture. This was done and the short tube (Symonds's No. 12, 6 in.) was then placed in position without any difficulty. The patient was able to swallow liquids freely and easily, the tube was not touched, and all went well till April 4th, eleven days later, when the patient suddenly collapsed, became very pale, brought up a large quantity of blood, and died in a few minutes.

Necropsy.—This was made by Dr. J. H. Bryant. There was found to be recent pleurisy at the right base and there were some old pleuritic adhesions over the front of the right lung; both lungs were emphysematous. There was a patch of septic broncho-pneumonia in the right lung, which was adjacent to the œsophageal growth, the bronchial glands were enlarged from deposit of secondary growth, and there were some patches of early atheroma in the ascending aorta. Seven inches from the commencement of the œsophagus was a carcinomatous growth which involved two and a quarter inches of the length of the tube; it was hard and had thickened the wall of the tube. The internal surface of the growth was ragged and ulcerated and the ulceration had extended through the coats of the aorta two and a quarter inches from the commencement of the descending aorta. The œsophagus was dilated above the stricture and the walls were thickened; in the mucous membrane at the upper part there were a few nodules of secondary growth. The stomach was distended and filled with a large blood clot.

Remarks by Dr. FREDERICK TAYLOR.—The above rapid termination of cancer of the œsophagus is sufficiently rare to make a case of its occurrence worthy of record. In 1885 I had a similar instance under my care which I published among some cases of malignant disease of the chest and abdomen,[4] and I took the opportunity of referring to eight other recorded cases. On May 20th, 1895, Stadelmann reported to the Berlin Society of Internal Medicine two cases of carcinoma of the œsophagus opening into the aorta; and at the same meeting Professor Ewald stated that in from forty to fifty cases of carcinoma of the œsophagus he had only known one to perforate the aorta.[5] Little, if at all, do the symptoms of cases differ from others of œsophageal cancer before the occurrence of the fatal hæmorrhage, but in a few there have been preliminary bleedings described as vomiting of blood. Generally the event is quite unforeseen. In most of the cases alluded to in my paper the opening in the aorta was in the lower part of the arch or the upper half of the thoracic aorta; in Stadelmann's two cases the cancers were situated respectively four inches and six inches above the cardiac orifice of the stomach. Any successful or even palliative treatment is, of course, out of the question.

GENERAL HOSPITAL, BIRMINGHAM.

A CASE OF INTRA-PERITONEAL RUPTURE OF THE URINARY BLADDER IN A WOMAN SUCCESSFULLY TREATED BY ABDOMINAL SECTION AND SUTURE.

(Under the care of Mr. GEORGE HEATON.)

THERE is at the present time no doubt as to the treatment required for intra-peritoneal rupture of the bladder due to injury. The rent should always be sutured and the peritoneum cleansed, provided it be possible to carry out the necessary procedure. The two conditions which are most likely to prevent a surgeon from adhering to this rule are excessive nervous shock and a hopeless state of the patient from urinary infiltration or as the result of peritonitis. Blum operated successfully on a patient forty hours after the accident, and healthy urine may remain in contact with peritoneum for some days without exciting fatal peritonitis, but success is most likely to be attained if operation be performed soon after the infliction of the damage, inability to make a diagnosis alone justifying delay. One of the most

important contributions to our literature on intra-peritoneal rupture of the bladder, that by Le Sieur,[1] contains a summary of 34 cases which had been submitted to operation. Of these, 14 recovered and 20 died, but we may expect a much better record in the future. It is probable that one of the chief difficulties in making a diagnosis has been met with because it is not recognised that the symptoms vary greatly in different cases, according to the nature of the injury, the condition of the bladder at the moment when the rupture occurred, the size and age of the patient, and the time which has elapsed since the injury was inflicted. Then, again, intra-peritoneal rupture of the bladder is known to be a very fatal injury, and it is difficult sometimes to understand that the healthy-looking patient who has walked up to the hospital and complains of inability to pass urine and a constant desire to micturate, is suffering from a ruptured bladder. Yet it may be so. Shock is one of the most fallacious signs in abdominal injury, and no reliance can be placed on the complete absence of discolouration of the skin. Rupture of any of the abdominal contents may be found without evidence of contusion of the parietes. Reliance must be placed on the history of the case, the result of examination of the abdomen, and the passage of a catheter. These points are well exemplified in the following case. For the clinical notes of the case we are indebted to Mr. S. Gill, house surgeon.

A housewife aged twenty-eight years was admitted into the General Hospital, Birmingham, on Aug. 19th, 1895, suffering from abdominal pain and inability to pass urine, the result of an accident. About 10 P.M. the previous evening she was "romping" with her husband in the sitting-room when he tripped and fell heavily on her. She was at the time lying on her back on the floor of the room, and he fell across her abdomen. She was at once seized with a severe burning pain in the lower part of the abdomen and had a severe attack of vomiting. With the pain she had a great desire to micturate, but found that she was quite unable to do so. A medical man was summoned and passed a soft catheter, drawing off a quantity of urine deeply stained with blood. The removal of the urine by the catheter relieved the straining efforts at micturition, but the pain gradually extended all over the abdomen and the vomiting continued at frequent intervals all that night. The patient had passed urine two hours before the accident occurred. She had an infant twelve months old whom she was still nursing. On admission into the hospital at 10 A.M. she complained of much abdominal pain and an intense desire to micturate. She was not actually sick, but complained much of nausea. The abdominal facies was well marked. There was much tenderness all over the abdomen, but chiefly in the hypogastrium and the right iliac region. Abdominal respiratory movements were absent in the lower half of the abdomen. There was some dulness in the left flank, but the right flank was resonant and the dulness did not alter with change of position. There was much muscular resistance to palpation in the hypogastrium. The temperature was 100° F. and the pulse 84, small and wiry. A soft catheter was passed and four ounces of urine deeply blood-stained were drawn off. At 1 P.M. Mr. Heaton passed a large silver catheter. This could be passed its entire length without meeting any resistance and could be plainly felt high up in the abdominal cavity beneath the abdominal wall. No urine appeared until it was withdrawn within three inches of its end, when four ounces of bloody urine escaped. Mr. Heaton and Mr. Haslam (who saw the case in consultation) agreed that there was in all probability a large rupture of the urinary bladder into the peritoneal cavity and advised an abdominal section without delay. At 1.45 P.M. (that is to say, fifteen hours after the accident) the patient was removed to the operating theatre and anæsthetised with a mixture of ether and chloroform. The abdomen was opened in the middle line below the umbilicus. On opening the peritoneal cavity a large quantity of blood-stained fluid welled up and escaped. On examining the pelvic organs with the finger a large ragged opening could be felt on the upper surface of the bladder. The incision was enlarged downwards and the bladder pulled up into the wound. A rent with torn edges from which the mucous membrane protruded was then seen on its upper and posterior aspect, extending from the summit backwards and slightly to the left. It measured three and a half inches in length. Some small portions of the everted mucous membrane were cut away and the rent sutured. The finest Chinese twist silk was used for suturing. The rent was first of all closed by a row of Jobert sutures passed through the serous and muscular coats about a quarter of an inch from the side of the rent and issuing on the torn muscular surface. A large number of these were passed about an eighth of an inch apart and tied. A second row of sutures was then passed after Lembert's method, passing through the serous and muscular coats on each side of the previous row of sutures. These were in like manner inserted an eighth of an inch apart, tied, and cut short. A third row was inserted in places along the rent where the union seemed to be at all weak. Some twenty or thirty sutures were passed in all. The bladder was then distended with warm water and found to be quite water-tight. The abdominal cavity was finally flushed with large quantities of water, previously boiled, at a temperature of 110° until the washings returned quite clear. The cavity was sponged as dry as possible and the abdominal incision closed with stout Chinese silk sutures. No drainage-tube was employed. The wound was dressed with iodoform gauze and absorbent wool, and a No 11 soft red-rubber catheter was left in the bladder. The patient bore the operation, which lasted nearly one hour and a half, very well, and suffered but little from shock. She vomited once at 10 P.M. that evening and again at 5 A.M. the next day, but she slept well after having a fifth of a grain of morphia injected subcutaneously. The symptoms gradually disappeared and on Sept. 2nd the urine was free from blood. No power of voluntary micturition returned until the 11th, and a catheter was passed every six hours until then. The bladder at times would distend so as to hold as much as twenty-eight ounces and yet the patient be unable to pass any urine unaided. A small hæmatoma formed in the sheath of the left rectus muscle which somewhat delayed the final closing of the abdominal wound, but this was soundly healed on the 20th, and on the 25th she was allowed to get up. She left the hospital on Oct. 3rd wearing an abdominal belt to support the operation scar. Micturition was quite normal and painless, and she could hold her urine without difficulty for eight hours.

Remarks by Mr. HEATON.—Abdominal section and suture of the rent for rupture of the urinary bladder, an operation which was first put into practice by Mr. Alfred Willett, has now been performed successfully some fifteen times. The accident, however, is of sufficient rarity to justify the publication of every attempt made, whether successful or unsuccessful, to avert what, if left alone, is invariably a fatal issue. This case is, as far as I can ascertain, the first recorded in which the lesion has been successfully dealt with in a woman, all the successful cases hitherto reported having been in males. This is doubtless due to the extreme rarity of the accident in women. The operation was a tedious and laborious one owing to the large size of the rent and the depth from the surface of its posterior angle. The insertion of a double instead of a single row of sutures, though it adds to the length of the operation, more firmly and securely closes the rent and so lessens the risk of leakage which has been one of the commonest causes of failure afterwards. In any future case I should be disposed to use two rows of Lembert sutures rather than an inner row brought out through the torn muscular surface. The slight attack of cystitis which my patient had during convalescence I consider to be probably due to one or two of my inner row of sutures having become exposed to the contact of urine in the bladder. I must take this opportunity of acknowledging the care and attention devoted to the case by Mr S. Gill and the nurses in charge of the case, to whose efforts the successful issue was in no small part due.

ROYAL MICROSCOPICAL SOCIETY.—The next meeting of this society will be held on Wednesday, April 15th, at eight o'clock.

THE BRISTOL ROYAL INFIRMARY.—The annual meeting of the subscribers of the Bristol Royal Infirmary was held on March 24th, under the presidency of Mr. C. D. Cave (president and treasurer). The report showed that 3103 in-patients and 33,536 out-patients had been treated during 1895. The average daily number of in-patients was 199·3, and the cost of each was £3 4*s.* 10*d.*, the average stay in the infirmary being 23·4 days. The ordinary expenditure for the year amounted to £12,575 and the extraordinary to £2347. The balance due to the treasurer, which stood at £6962 at the end of 1894, was £8755 on Dec. 31st, 1895.

Medical Societies.

BEDFORD MEDICAL SOCIETY.

President's Address.—Diphtheria.—Exhibition of Specimens.

THE first meeting of this society was held on March 26th at the Bedford Infirmary, Dr. G. P. GOLDSMITH, the President, being in the chair.

The PRESIDENT, in his opening address, described the objects of the society and laid stress on the advantages to be derived by members from a society whose chief objects are the reading of cases and exhibition of specimens.

The President read a paper on Acromegaly and showed a woman aged thirty suffering from this disease. For two years she had suffered from amenorrhœa and had noticed a gradual enlargement of her hands and feet. The lower jaw was also enlarged and there was marked exophthalmos. There was no headache or evident affection of vision. The skin was usually clammy. There was no apparent affection of the thyroid gland.

Dr. WILLMER PHILLIPS and Mr. KINSEY read notes of a severe case of Diphtheria treated by Antitoxin Injections and Tracheotomy and showed the patient.

Mr. KINSEY read notes of another case of Diphtheria which recovered under antitoxin treatment.

Dr. ROWLAND COOMBS read notes of a case of Carcinoma involving the Lesser Curvature of the Stomach and the Pancreas and showed the specimen. The patient, a man aged thirty-five, had an infiltrating mass in the epigastric region, with slight fever and progressive loss of flesh. Vomiting was practically absent. There was an enlarged gland in the left groin, and post mortem the iliac, mesenteric, lumbar, and mediastinal glands were found to be enlarged. The liver was not affected.

The following specimens were shown :—

Dr. COOMBS : Kidneys and Heart from a case of Chronic Nephritis.

Mr. COLBY SHARPIN : Periosteal Sarcoma of the Lower End of the Femur through which a fracture had occurred from a slight cause.

Dr. HARVEY GOLDSMITH : (1) Heart with extensive Calcification of the Mitral Valves ; (2) Brain with Symmetrical Tumours of the Frontal Lobes ; and (3) Two Spinal Cords showing Ascending Degeneration.

Mr. KINSEY : Carcinoma of the Rectum.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—The Possible Dangers of treating Extensive Burns with Boracic Ointment.—Hæmorrhagic Salpingitis.

A MEETING of this society was held on March 12th, the President, Dr. PORTER, being in the chair.

Dr. MAUNSELL (Rotherham) showed three patients (who were related) suffering from Congenital Onychatrophia and other malformations of the fingers and toes. A detailed family history was given, tracing back the abnormalities through several generations.

Mr. CUFF showed a Larynx embedded in the substance of the arytenoid muscle of which was a circumscribed, non-encapsuled Tumour. The growth, which was about the size of a pea, was of a greyish pink colour, and that part abutting upon the arytenoid cartilage was breaking down, a sinus leading from the posterior end of the laryngeal sacculus directly backwards into this softened tissue, at the bottom of which was the exposed and bare cartilage. The tumour was believed to be a gumma. The patient, who had had syphilis and also later ague in India, came under treatment for splenic anæmia. Œdema of the larynx supervened. On laryngoscopic examination great tumefaction and redness of the whole glottis were revealed. The swelling was more marked on the right side. On the upper surface of the epiglottis an irregular ulcer with a yellowish base and injected margin was to be observed. The diagnosis of syphilitic perichondritis was made from the history and the laryngoscopic appearances.

Dr. ARTHUR HALL read a short paper on the Possible Dangers of treating Extensive Burns with Boracic Ointment. The case which formed the text of the paper was one of a boy who was admitted, with extensive burns, into the Sheffield Royal Hospital under the care of Dr. Sinclair White. He was treated as usual with unguentum boracis. On the fifth day he developed an extensive erythematous eruption over the limbs, trunk, and face, for which Dr. Hall was asked to see him. During the next few days he gradually became worse and died on the ninth day. At the necropsy nothing was found to account for death, and previously to the eruption the boy was doing very well. There were no throat symptoms whatever ; there was delirium at night ; the rash developed more each day. Dr. Hall quoted many recorded cases of similar groups of symptoms occurring definitely from boracic acid poisoning, and pointed out that the extent of surface for possible absorption was very great, and, although not pressing the connexion between the boracic acid and the symptoms, thought that if there was no connexion between the two, still the occurrence of such fatal symptoms was worthy of more extended inquiry than was at present given with a view to preventing their occurrence by a more rigid antiseptic treatment.

Dr. ANDREW WALKER read a paper on Hæmorrhagic Salpingitis, which was illustrated by numerous microscopic slides and drawings.

The PRESIDENT, Dr. RUTHERFORD, Dr. BURGESS, Mr. PYE-SMITH, Mr. EDWARD BARBER, Mr. CLYDE HAYES, Dr. ERNEST KNIGHT, and Mr. CUFF made remarks.

PLYMOUTH MEDICAL SOCIETY.

Exhibition of Cases and Specimens.

A CLINICAL meeting of this society was held on March 21st, Dr. HINGSTON, President, being in the chair.

Mr. J. MORRIS showed (1) a well-marked case of Pseudo-hypertrophic Paralysis in the second stage in a boy aged eight years, now under the care of Mr. Leah ; and (2) a girl aged seven years with a Bifid Uvula.

Mr. C. E. RUSSEL RENDLE showed (1) three generations in one family, aged ten, thirty-nine, and fifty-nine years respectively, with well-marked Lamellar Cataract—he also showed the "family tree" ; and (2) a Bony Plate perforated by the Central Artery of the Retina found in the choroid of an eye removed from a woman aged forty-three for panophthalmitis.

Mr. LUCY exhibited (1) an old Fracture in the outer fourth of the Right Clavicle in a male aged fifty-six years ; and (2) a haulier aged thirty years with marked Prominence of each Acromial End of his Clavicles and Lax Acromio-clavicular Joints, allowing of apparent luxation of the latter.

Mr. WOOLLCOMBE exhibited (1) Photographs of a man aged fifty years whose Posterior Ulnar Ridges presented three Symmetrical Nodes (there was a history of two attacks of acute rheumatism but no peri- or endo-cardial mischief) ; and (2) a Slide of Tuberculous Tissue prepared and exhibited by Dr. Webber. The deposit occurred on the dorsum of the hand of a woman aged forty-five years and was found to occupy pits on either side of the head of a metacarpal bone.

Dr. PETHYBRIDGE showed (1) a Slide of Diphtheritic Membrane showing Löffler's Bacilli *in situ*, and (2) Slide of Bacteria of the Mouth.

Mr. HAMILTON showed a case of Necrosed Phalanx with Fracture of the Distal End, apparently caused by a splinter of wood which at the same time set up destructive suppuration in the finger removed.

Mr. E. SQUARE exhibited a specimen of an Eye showing Retinal Detachment and a Plate of Bone in the Choroid in a male aged fifty-five years.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on April 3rd, Mr. H. E. CLARK being in the chair.

Dr. T. K. MONRO showed a boy who had suffered from Symptoms of Intracranial Tumour, but who was now in good health except that he was almost blind as a result of optic

Digitized by Google

nerve atrophy. The knee-jerks were entirely absent. The history of severe headache, vomiting, and subsequently slight strabismus and failure of sight dated back nearly two years. The symptoms followed a fall on the forehead. There was some evidence of tubercle in the family history and in the patient himself. There was also distinct enlargement of the cervical lymphatic glands. It was suggested that the tumour was probably tuberculous and situated in the cerebellum.—Dr. Monro also showed a specimen of a Myxomatous Tumour found in the cerebellum of a man who had died, aged sixty-three years, from cancer of the pylorus, and related the history of the patient as bearing on the previous case. At sixteen years the patient had a severe illness which lasted for fully twelve months, was accompanied by pain in the head, and was followed by loss of sight in both eyes. He had been at the time of his death an inmate of the Blind Asylum for thirty-three years, and had during his residence enjoyed good health. When examined there was extreme atrophy of each disc; the gait was unaffected and the knee-jerks were normal. Post-mortem examination revealed the tumour in the left lobe of the cerebellum with atrophy of the optic nerves and chiasma.—Dr. Monro also read notes of a case of Melæna Neonatorum. The child had died on the third day after birth, and on post-mortem examination the stomach and intestines were found filled with blood. The blood appeared to have escaped from a small linear ulcer situated close to the cardiac orifice of the stomach.—Dr. WM. RUSSELL described two similar cases, in one of which, however, the patient survived.

Dr. W. K. HUNTER showed Cultures and Microscopic Specimens of a Micro-organism which he had observed in the blood of two patients suffering from Beri-beri. Inoculation experiments are to be undertaken with a view to determine whether the micro-organism is or is not the cause of the disease.

Dr. BELL TODD read notes upon the Varieties of Oil of Eucalyptus at present used in Medicine and exhibited a large number of specimens. He discussed the various botanical sources of the oils and pointed out that numerous specimens at present on the market were quite destitute of eucalyptol, though their antiseptic properties were undoubted. He had found the internal administration of the oil of value in gonorrhœa as an agreeable substitute for sandal-wood oil, &c., and he had successfully treated several cases of tape-worm by ordering oil of eucalyptus.

Dr. A. N. MCGREGOR showed the Brain and Right Lower Limb removed from the body of a boy the subject of marked unilateral hypertrophy; photographs of the patient were also exhibited. The boy at the time of his death was twelve years of age, and whilst the right lower limb had always been "weak" definite enlargement had been observed for six years. Latterly the size of the limb had caused him so much annoyance and so seriously interfered with his freedom in walking that the parents and the boy himself solicited amputation. This was decided on and the limb was amputated above the knee. The operation was attended by troublesome hæmorrhage and the boy subsequently became very excited; vomiting became troublesome and was attended by hæmatemesis, and in the end he succumbed forty-eight hours after the operation. Post-mortem examination revealed some enlargement and thickening of the optic chiasma and considerable increase in size of the right optic thalamus by a new growth the exact nature of which has yet to be determined; the pituitary body was normal in appearance. There were some evidences of tubercle in each lung, otherwise the viscera were healthy. Dr. McGregor drew attention to the special feature of the case—viz., the association of a tumour in one side of the base of the brain with a unilateral hypertrophy—and remarked upon the existence of this tumour without any symptoms pointing to its presence.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

The Testing of Drinking-water for the Bacillus Coli.

A MEETING of this section was held on March 13th, Mr. CONOLLY NORMAN, President, being in the chair.

Dr. M'WEENEY gave a demonstration of Some Recent Methods of testing Drinking-water for the Bacillus Coli. When outbreaks of typhoid fever were traceable to drinking-water it was seldom that perfect demonstration of Eberth's bacillus in the water was effected, for the period of specific contamination was often at an end before the water was examined. All hygienists, however, agree that the presence of the bacillus coli possesses a high significance as affording evidence of the possibility of specific contamination. He then showed the results of three modern tests—Parietti's, Von Frendenreich's, and Abba's—which had been applied to three samples of water. Each sample consisted of half a litre of Vartry water drawn off into a clean flask forty-eight hours previously. To flask No. 1 there was added a trace of typhoid fæces obtained by once dipping a straight platinum needle into the fæces and then into the water. To flask No. 2 there was added a trace of pure culture of the bacillus coli, *var. lactis aerogenes*, from the fæces of a suckling infant. The water in flask No. 3 was left untouched. After twenty-four hours Parietti's test was performed, half a c.c. of each water being added to a series of tubes containing broth acidified with hydrochloric acid and mixed with phenol in various proportions. The tubes were then shown after twenty-four hours' incubation, when it was at once seen that those corresponding to the infected samples were turbid, whilst the uninfected were limpid and showed no signs of growth. Von Frendenreich's and Abba's methods depend on the ability of the bacillus coli to develop at blood heat in solutions containing lactose. Von Frendenreich causes this to take place in a fermentation-tube (as originally recommended by Th. Smith of Washington), and observes whether gas has accumulated in the closed side at the end of twenty-four hours. The present samples showed that one-third of the fluid in one tube (that corresponding to the typhoid sample), and nearly two-thirds in the other (the bacillus coli sample), had been expelled from the closed limb by gas. The pure sample had not evolved the smallest bubble. Abba's method consists in converting the whole sample, or one litre of it, into a nutrient solution by the addition of 100 c.c. of a concentrated solution of peptone and lactose, then adding a little phenolphthalein and imparting a rose colour with soda. After twenty-four hours' incubation the samples inoculated with the typhoid stools and the bacillus coli were completely decolourised and turbid, whilst the pure sample showed but little growth and was not in the least decolourised, as was shown by comparison with an unincubated portion. The bleaching of the two infected specimens was, of course, caused by the neutralisation of the alkali by the lactic acid developed from the fermentation of lactose by the action of the bacillus coli. All three methods yielded, on plating out the fluid, abundant colonies of bacillus coli. Whilst Parietti's method permitted only quantities under 1 c.c. to be used and Von Frendenreich's about 5 c.c., Abba's method placed the analyst in a position to detect colon bacilli in a litre of the water. Too much importance ought not, however, to be attached to the presence of small numbers of bacillus coli in water. The originally sterile intestine of the breast-fed infant comes to contain this organism in millions a few days after birth, a fact pointing to its universal diffusion through the air. It was only when present in large numbers, and associated with organic matter capable of affording it pabulum, that its presence could cause the condemnation of the water.—Dr. O'SULLIVAN asked what was the time limit of the changes diagnostic of the bacillus coli communis, for other bacilli—the diphtheria bacillus, for instance—also caused acidity of the medium in which they grew.—Dr. PARSONS pointed out that the tests were tests not for the typhoid bacillus but for the bacillus coli communis. Formerly, from a bacteriological point of view, water was considered bad which contained a great number of micro-organisms. Now, if the bacillus coli communis was present in large numbers the water was rejected, as it showed probability of the water having been contaminated. If only a few were found it was not looked upon as impure. He wished to know whether the tests they had seen would show the typhoid bacillus in the urine; also whether the bacillus coli communis was present in the urine of typhoid fever patients.—Dr. M'WEENEY, replying, said with reference to the time limit no attention should be given to any result that took over twenty-four hours to develop. It was true that other organisms made the medium acid, but they were distinguished from the bacillus coli communis by their not developing in a solution containing a large quantity of lactose. He could not, however, speak with certainty of the diphtheria bacillus. Two of the tests were not for the typhoid bacillus, but Parietti's

Digitized by Google

test reacted to both it and the bacillus coli communis, and by plating out it was easy to know which was present. He did not believe that there was an essential distinction between the typhoid bacillus and the bacillus coli communis. The four characters which distinguish them—viz., the growth on potato, the mobility, the fermentation of lactose, and the coagulation of milk — are all mutable. As regards the fermentation, however, he had only found it to occur with the colon bacillus. There are clinical facts which show that auto-infection from one's own bowels may take place, and the bacillus coli communis may set up inflammation in Peyer's patches, and toxic substances may be absorbed giving rise to symptoms the same as in typhoid fever. He did not know whether a rash would be present or not. Parietti's tests would enable the typhoid bacillus to be found in the urine, but in any catarrhal or inflammatory condition of the urinary tract the bacillus coli communis would also be present.

Reviews and Notices of Books.

Diseases of the Nose and Pharynx. By J. B. BALL, M.D. Lond., M.R.C.P. Second Edition, with 49 Illustrations. London: Baillière, Tindall, and Cox. 1894.

Diseases of the Throat, Nose, and Ear: a Clinical Manual for Students and Practitioners. By P. MCBRIDE, M.D., F.R.C.P. Edin. Second Edition, Revised and Enlarged, with Coloured Illustrations from Original Drawings. London and Edinburgh: Young J. Pentland. 1894.

A Treatise on Diseases of the Ear, including the Anatomy and Physiology of the Organ, together with the Treatment of the Affections of the Nose and Pharynx which conduce to Aural Disease. By T. MARK HOVELL, F.R.C.S. Edin., M.R.C.S. Eng. London: J. & A. Churchill. 1894. Price 18*s*.

Diseases of the Ear: a Text-book for Practitioners and Students of Medicine. By EDWARD B. DENCH, Ph.B., M.D. With 8 Coloured Plates and 152 Illustrations in the text. London: Henry Kimpton and Hirschfeld Brothers. 1895. Price 21*s*.

OF these works the books of Dr. Ball and Dr. McBride are second editions, while those of Mr. Hovell and Dr. Dench come before the profession for the first time. We propose to review them in the order of their publication. The first edition of Dr. Ball's book, published in 1890, was limited to the nose and naso-pharynx, the second includes the pharynx also. The first thirty-five pages are devoted to anatomical and physiological descriptions, and might, we think, be omitted with advantage as they are not full enough to be of real value to the student and nothing in the way of original observation has been contributed. The chapter on General Diagnosis is fairly good, but more might with advantage be added concerning palpation of the pharynx. In the chapters on Inflammatory Conditions of the Nasal Cavities the directions for treatment are concise, but the variety of methods mentioned show no accentuation—they are all put in line before the reader; very rarely does the author indicate his preference for a particular mode of treatment, and still more rarely does he give his reasons for so doing. There is, moreover, a needless subdivision of headings, as the remarks on acute and chronic naso-pharyngitis might well have been incorporated with the preceding chapters.

A clear description of adenoid vegetations is given, but under physical examination we fail to see the necessity of insisting on posterior rhinoscopy in addition to digital palpation in a well-marked case in a child. For removing the growths Dr. Ball prefers Rualt's forceps with the patient chloroformed, the head hanging down over the edge of the table and the neck not over-extended. He considers local after-treatment unnecessary.

The treatment of hay fever is fully discussed, and with regard to local measures Dr. Ball writes that "intra-nasal treatment is not necessarily to be discarded from consideration because no gross pathological changes are present, for since the attack is immediately determined by the application of an irritant (pollen) to the nasal mucous membrane, any treatment which has been found to destroy the irritability of the mucous membrane, such as the destruction of hyperæsthetic areas with the galvano-cautery, is rational." The author's remarks on the treatment of nasal polypi are sensible and up to date. He prefers the cold snare to the galvano-cautery. In discussing the treatment of suppuration in the antrum of Highmore we think that sufficient emphasis is not laid on the advantages of the dry method of treatment by way of an aperture made through the canine fossa. The work closes with some chapters devoted to the consideration of diseases of the pharynx, which, in view of recent advances of our knowledge in this direction, will require radical revision. The most disappointing part of the work is the illustrations. These are forty-nine in number. No less than thirty-eight of them are from instrument-makers' catalogues, and with a few typical exceptions these might be omitted. Of the remaining eleven, nine are illustrations of the anatomical portion of the work, eight of these being acknowledged copies from well-known text-books. This leaves two illustrations for the whole volume of diseases of the nose and pharynx. One of these will be found to be a copy of a diagram in Mr. Butlin's work and the other is a portrait of a boy with adenoids. In a future edition we hope the author will reproduce from his note-books at least half-a-dozen original pictures of the many morbid processes he describes. The book is well got up and of a handy size for the reader.

Dr. McBride's work is, we think, still the best before the medical public both for student and practitioner. In the matter of illustrations, compared with Dr. Ball he has gone to the other extreme and has omitted instruments altogether. We have already said that we think one type of each instrument, recommended by the author from experience, would assist a general practitioner considerably in his choice, though a good answer to this is that the illustrated catalogues of all the instrument makers are always at the disposal of any intending purchaser. The pictures in Dr. McBride's book are all original and are well reproduced, if we except one or two in the division of the work devoted to nasal diseases, upon which we remarked when criticising the first edition in 1892. Dr. McBride's strong point throughout the work is his energetic advocacy of general treatment in all the local lesions he discusses, a point so often overlooked altogether by specialists. In removing enlarged tonsils he prefers Renier's instrument, though we imagine that most surgeons are content with Mackenzie's simpler guillotine, which is so much easier to clean. In the section on Chronic Infective Diseases of the Pharynx we see no reason for describing tubercle and lupus under separate headings. The chapter on Laryngeal Phthisis is well written and the criticism of some recent methods of modern treatment judicious and not at all too severe. Dr. McBride is unable to speak decidedly as to the advisability of attempting to extirpate malignant disease of the larynx by the endo-laryngeal operation.

The chapter on the Remote Effects of Nasal Disease, with special reference to Nasal Reflex Neuroses, has been rewritten and the position taken up with regard to this difficult subject is a sound one. We agree with Dr. McBride when he says that the danger to the middle ear from the employment of the nasal douche has been over-estimated. In dealing with nasal polypi, in common with most modern rhinologists, he employs the cold steel wire snare, and as after-treatment he advises the employment of a spray of rectified spirit twice daily for a month and afterwards to repeat it on the slightest indication of "stuffiness." Dealing with

Digitized by Google

adenoid vegetations of the naso-pharynx he prefers Gottstein's curette, with the patient under chloroform and the head hanging over the edge of the table. He employs no after-treatment. In discussing the methods of examination for ear disease the author states that he has as yet seen or read nothing which has convinced him that in really doubtful cases either Weber's or Rinné's experiments can be considered of any real value. In the treatment of eczema of the meatus he recommends strongly the application of a solution of nitrate of silver in spirit of nitrous ether. With regard to aural exostosis, it is held that operative treatment is only justified when the other ear is deaf or when there are symptoms pointing to retention of pus. The chapter on acute inflammation of the middle ear is well written and the author is in accord with most authorities on the subject when he says that the insufflation of powders should not be practised in the case of small perforations of the tympanic membrane. Stacke's operation and its modifications are discussed fully, and the author states his preference for chisels and gouges for opening the bone while the burr is the better instrument for the deeper work. In discussing the subject of chronic non-suppurative inflammation he relates the operative achievements of the American and continental schools, but adds that he does not follow them in this direction beyond section of the posterior fold of the membrana tympani. We think that the attitude here taken up will be supported by the great majority of English otologists. We base our confidence in recommending this work to the general reader who requires information about the throat, nose, and ear on the facts that the book is an eminently practical one and that the directions for treatment are stated with clearness and conciseness. The arrangement and printing of the work are excellent, but it would be a great improvement if marginal references were introduced.

Mr. Mark Hovell's volume is, as the preface tells us, addressed particularly to those members of the profession who feel themselves drawn to give special attention to a department the importance of which, he regrets to say, is still only partially recognised. There are eighty-five pages devoted to anatomical and physiological remarks on the organ of hearing, and, as we have stated above, we think that readers might have referred for this information to current text-books on these subjects. The chapter upon the examination of the ear and the determination of the hearing power is well written. Mr. Hovell prefers Brunton's otoscope, believing that it gives a better view than with simpler apparatus, but we doubt if even for diagnostic purposes he will find the majority of aural surgeons at one with him on this point. He refers to Rinné's test as a means of distinguishing between affections of the middle ear and disorders of the auditory nerve, provided that it be considered in connexion with the degree of deafness as regards speech and with altered perceptive capacity for various notes. Very precise directions are given for the passage of the Eustachian catheter, and the use of Eustachian bougies is condemned, as he believes that they are capable of causing serious mischief. The chapter on Hæmatoma Auris has for its alternative heading "Vascular Tumours of the Auricle." This is surely an objectionable title, for a vascular tumour is a distinct pathological entity, an angeioma and not a hæmatoma. The chapter on Eczema of the Auricle and Meatus is well written, but it seems to us a needless task to subdivide, as of old, dermatitis of the external ear into the eczematous, the circumscribed, the diffuse, the croupous, the diphtheritic, the parasitic, and the syphilitic varieties. The account of new formations of the external ear is full and precise, but under the head of angeioma of the auricle we miss any reference to treatment by injection of carbolic acid; and in discussing the removal of exostoses, though a full account is given of various operative methods, no mention is made of the simple process of removing the exostosis by taking away the portion of the meatal wall from which it grows, a procedure far more easily accomplished than is the rule where the drill is used, as the bone of the meatus is so much softer. Some of the commoner diseases of the nose and naso-pharynx are described, and the author, in enumerating the various modes of treatment, pronounces, too strongly we think, against the use of the nasal douche. He prefers, with the majority of surgeons, to use a snare for the extraction of nasal polypi, but he is perhaps a little too severe upon those who still use the forceps. It is certain that after cocaine nasal polypi can be painlessly removed by forceps, and that surgeons who constantly practise this method acquire a tactile skill in the application of the forceps unknown to those who are not accustomed to it. Mr. Hovell prefers to perform tonsillotomy without an anæsthetic, and gives his adhesion to Mackenzie's instrument as the best. He mentions that to check hæmorrhage after tonsillotomy he has found excellent results follow rubbing firmly against the bleeding surface a hard paste made of three parts tannic acid and one part gallic acid, with a few drops of water. He recommends sucking ice or lozenges after the operation, but we would join issue with him here and prefer that the patient should avoid suction and keep the mouth open. In cases where enlarged tonsils and adenoid growths are associated Mr. Hovell prefers to remove the tonsils at a first sitting. For removal of adenoids he directs that a general anæsthetic should be administered, the patient being placed on his back with the head slightly extended, and the growth removed with a forceps which he has modified from Löwenberg's pattern. After the operation he sprays a weak antiseptic solution through the nostrils into the naso-pharynx several times daily.

In discussing the question of excision of the ossicles in chronic adhesive catarrh of the middle ear Mr. Hovell rightly doubts whether such severe measures are really justifiable while the indications for their adoption are so imperfectly defined as they are at present. He looks upon artificial perforation of the tympanic membrane as more useful for diagnostic than remedial purposes, and he refers to division of the tensor tympani as an operation of very doubtful benefit; any advantage is but slight, and its results are not infrequently mischievous. The subjects of acute and chronic suppurative inflammation of the middle ear are fully dealt with, and in the article on Persistent Perforation the author, after referring to the best of so-called artificial membranes on the market, states that, on the whole, the best substitute for the natural tympanic membrane is a cotton ball or pellet impregnated with boric acid, salicylic acid, or thymol, and then moistened with diluted glycerine.

In the treatment of aural polypi the author rightly places the removal of the cause before the removal of the polypus itself, the latter being effected by the snare and curette. In dealing with caries of the tympanic roof the method of operating devised by Stacke is described and the various methods of operating in mastoid disease are fully given. The cerebral complications of ear disease are clearly related, and the origin of general tuberculosis and tuberculous meningitis from mastoid and tympanic tuberculous deposits are supported by the observations of Dr. Barr upon these points. The work closes with chapters upon the abstruse subject of internal ear disease and with a useful article on diseases of the ear in relation to life insurance. The whole book is well got up, with large type very clearly printed. With regard to the illustrations, these are 122 in number; 19 of them are copies of anatomical plates and 71 are pictures of instruments. Of the remaining 32, 24 are original drawings by the author, chiefly of morbid conditions of the tympanic membrane and of sections of polypi. The

Digitized by Google

work is a readable and trustworthy representative of English opinion on otology.

Dr. Dench's textbook is addressed to practitioners and students of medicine and is of rather smaller size than Mr. Hovell's work. In his preface he takes up a defensive attitude with regard to his advocacy of operative procedures upon the middle ear, and suggests that the favourable outcome of his operations has depended upon a judicious selection of suitable cases. The work is illustrated by eight coloured plates and 152 illustrations in the text. Of the coloured plates those illustrating the vascular and nervous supply of the ear are ingenious and useful; the reproductions of the tympanitic membrane are particularly good, but the last two plates, intended to represent the mastoid operation and operations for intracranial complications, are crude in colour and drawing. Of the illustrations in the text 58 are pictures of instruments, 32 are anatomical drawings, and 62 illustrate the subject clinically. Of the anatomical drawings, 17 are original, and the majority of these are beautifully produced photogravures of the author's own specimens. They of themselves are an ample apology for the introduction of an anatomical section into the work. Of the clinical illustrations, no less than 54 are original, many of these being faithful reproductions of common lesions in disease of the middle and external ear. They derive additional advantage from being made of life-size and showing in section the auricle, meatus, and middle ear in the same drawing. In some cases, however, where the desire is to exhibit an operation upon the middle ear, the author would have produced a more intelligent picture if he had enlarged it. The chapter on Physical Examination is full and trustworthy. Preference is given to pure silver as the best material for a Eustachian catheter on account of the ease with which its curve can be moulded without diminishing its lumen. Under the head of Functional Examination, when discussing the value of Rinné's test, the author points out that the accumulation of clinical evidence from the investigation of a large number of cases has convinced those interested in otology that in many instances it cannot be relied upon to indicate the site of the lesion. In his efforts to be thorough Dr. Dench frequently becomes diffuse. Surely it is not necessary, when dealing with the subject of boil of the meatus, even if it be labeled "otitis externa circumscripta acuta," to devote more than eight pages to its description and diagnosis and follow with ten closely printed folios of treatment—treatment by heat and treatment by cold, with leeches natural and artificial—and then remark towards the end of all this what ought to have been stated at first—namely, that early incision is the best mode of dealing with the affection.

The same charge of unnecessary prolixity may be brought against the chapters on Diffuse External Otitis. In the treatment of the chronic form of this affection mention is made of the value of the application of boric acid and other powders to the surface, and it is added "these measures should not be trusted to the hands of the patient, but should be carried out by the surgeon, at first daily, the interval being increased as the case progresses." We cannot too strongly deprecate this advocacy of the constant attendance of the medical man, at great expense to the patient, to carry out a detail of treatment which can be quite safely entrusted to the patient himself. It is certainly not necessary for the surgeon himself to syringe away epithelial débris and insufflate boric acid every day in these cases, any more than it is wise or just so to conduct a case of furuncle in the ear that the surgeon himself must see the patient *twice* daily.

Dealing with the subject of Impacted Cerumen Dr. Dench insists that the collection should be removed at the first sitting, because the instillation of an alkaline solution with a view to soften the mass may cause it to swell and produce intense suffering from the great pressure exerted upon the walls of the meatus. The treatment of foreign bodies in the canal and of exostoses is fully described, and the recommendations are practical and good. In cases of tubal catarrh where the tube cannot be opened by inflation Dr. Dench uses a bougie, either employing a special bougie catheter or a piece of No. 5 piano wire passed through an ordinary catheter and armed at its roughened extremity with a pledget of cotton. This method of treatment which is here described without any attempt at advocacy has never found favour amongst English otologists. It appears to us that the chapters on tubal congestion and tubo-tympanic congestion might well have been included under the description of otitis media which follows. In dealing with otitis media we feel bound to call attention once more to the fact that the chapters might be reduced to one-third of their bulk without the omission of a single important fact. Chronic hypertrophic otitis media is described as to its etiology, pathology, symptomatology, diagnosis, prognosis, and treatment in twenty-two pages, and then follows chronic hyperplastic otitis media, similarly dealt with at length in fourteen more pages. Considering that if pus should be present a new affection, chronic purulent otitis media, is established, and twenty-eight further pages are devoted to this, while the results of former attacks receive, under the title of Otitis Media Purulenta Residua, a further fifteen pages, the question arises if every patch of mucous membrane in the body were similarly honoured how many volumes a work on general surgery or medicine would run to. Surely there is no essential difference between the mucous membrane of the middle ear and of other parts, and the tendencies of chronic inflammation of it are the same, whether towards simple resolution, towards chronic catarrh and repair with fibrous thickening, or towards suppuration and resulting cicatrisation. It is obviously inaccurate and unscientific to differentiate the pathological accidents on the path of cure and elevate them into separate diseases with a separate etiology and pathology.

The variations in structure of the mastoid are well described, and this is followed by a description of the course and treatment of mastoid inflammation and its results.

A separate chapter is devoted to Middle-ear Operations. It is very full, and as Dr. Dench has elsewhere fully published his results, and they have been already much criticised, we will content ourselves with adding that he is a warm advocate of these intra-tympanic measures, not only for cases where there is actual perforation with purulent discharge, but in cases with whole membrane accompanied by deafness where the hearing has failed to improve under less radical measures. He candidly tells his patients of the experimental nature of the operative measures and recommends an exploratory tympanotomy. We can only add that the good results he details have not been generally obtained in this country, in spite of a very careful selection of cases, and we venture to hope that Dr. Dench will later collect the whole of his cases, giving full details of the former condition of hearing, the nature of the operation, the after-history as to pain and discharge, and the present state of the hearing. It is only by good results recorded in such a manner that these operations can deserve to come into favour. The closing pages of the work deal with Inflammation of the Labyrinth and its Treatment, the Effect of Acute Infectious Diseases, the Various Affections which are Complicated by Aural Trouble, and Deaf-mutism. A few words at the end are devoted to Diseases of the Nose and Naso-pharynx, and these might with advantage have been a little fuller.

Digitized by Google

For removal of adenoids he prefers general anæsthesia, the head of the patient being thrown backward over the edge of the table, and the growth removed with forceps, any small masses left being swept away by the curette.

In conclusion, we may say that Dr. Dench has made a painstaking effort to place the whole subject of aural surgery before the profession, that there are many good qualities in his work, and a judicious revision of another edition, while greatly reducing its bulk, would tend in other directions to make the work a more acceptable guide for the use of the profession at large.

LIBRARY TABLE.

Annales de l'Institut Pasteur. Edited by M. E. DUCLAUX. Vol. X., No. 3. March, 1896. Paris: G. Masson.—This number contains several articles of great general interest. The first is by M. Duclaux giving the results of a very prolonged and patient research on the chemical action of sunshine at different altitudes in different states of weather and at different times of year. He employed a solution of oxalic acid for estimating the chemical change, as this solution is not acted on by thermal rays, while under the influence of light it absorbs oxygen and is converted into carbonic acid with a negligible trace of formic acid. By estimating the acidity by titration before and after exposure to light the amount of oxalic acid consumed can be accurately measured. The results showed that in wet, cloudy weather there was little chemical reaction. On the days in which there was active chemical change there was sometimes bright sunshine, but often better effects were obtained when the sky was covered with fleecy clouds. Every photographer knows that these latter days are also best for printing from negatives. M. Duclaux suggests that these variations are due to the greater quantity of aromatic oils and other odorous vapours present in the air on fine clear days and asserts that they obstruct the actinic rays. This seems to require more proof than is given in the paper. Dr. de Haan of Java gives an account of the method he has employed for obtaining abundant lymph for vaccination by inoculating heifers from the arm of the human subject. He has inoculated monkeys (Macacus sinicus) from the heifers and subsequently from one another, and obtains pustules which run an exactly similar course to those in man. He has not considered it justifiable at present to inoculate from the monkeys to children. Dr. Hankin sends a very important preliminary note on the effect that the water of the Jumna and Ganges has in destroying the cholera bacillus. Water taken from the stream, or even from a corpse that has been macerating some time in the river, destroys the bacilli in pure cultures in the course of an hour or two. Dr. Hankin believes this action to be due to the presence of certain volatile acids, for the bactericidal power of the water is destroyed by boiling or even by allowing it to filter through the soil into shallow wells. The bacilli will flourish in boiled river water. There is also a preliminary report by Dr. David Bruce on the disease caused by the tsetse fly. He believes that the fly itself does not secrete the poison, and that its bite is only harmful by conveying parasites from another animal suffering from nagana, as the disease is called. He states that nagana can also be communicated by direct inoculation from one animal to another.

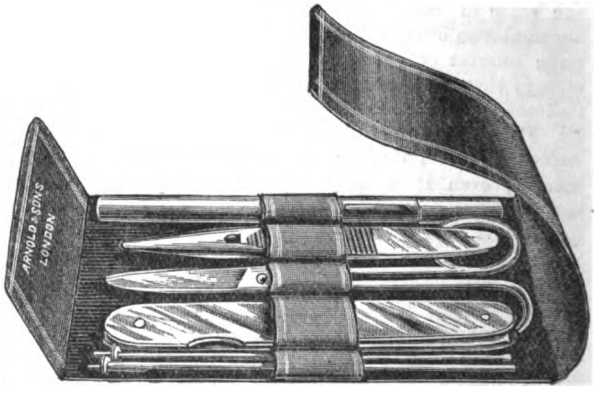
New York County Medical Association: Register of Members and Manual of Information. New York: Published by the Association. 1895.—This volume not only supplies in a clear and well-arranged form a large amount of information relative to medical organisations in the State of New York, but is practically a medical directory for the city. The association was founded in 1884, and in June, 1895, it consisted of 1056 members, whose addresses in New York, together with the description and dates of their qualifications, are published in full; a supplementary list gives the names and addresses of about 1780 well-recognised New York practitioners who are not members of the association. The main objects of the association are the maintenance of a high standard of professional ethics and the cultivation of medical and sanitary science. It is affiliated to the American Medical Association and meets every month. The secretaries are Dr. Nathan Gross Bozeman, 9, West Thirty-first-street, and Dr. P. Brynberg Porter, 150, West Eighty-fourth-street, New York, U.S.A.

No. 3 of *Architecture*, the new monthly magazine of architectural art, well maintains the excellent quality of its predecessors, being both profusely and well illustrated. The article on Westminster Abbey, No. 1 of the series on the Abbeys and Cathedrals of the World, is concluded, and the several pictures of the various parts of the historic building will doubtless be prized by many. At the moderate price of 1*s.* per month the magazine deserves well of all interested in architectural art. It is published at Talbot House, Arundel-street, Strand.

New Inventions.

IMPROVED POCKET CASE.

MESSRS. ARNOLD AND SONS of West Smithfield have made a pocket-case for me which has some advantages over those generally used. The ordinary case is far too bulky to be constantly carried. Most miniature cases consist of at least three thicknesses of stiffened leather with side flaps and a clumsy fastening. They do not fold well and contain instruments so small as to be practically useless. The case shown in the drawing is made of flexible morocco leather. It is four inches long, two inches wide, and about a third of an inch



thick. It contains: (1) scissors, one point sharp and the other blunt; (2) dissecting forceps, with spring catch, so as to act as artery forceps; (3) knife handle, with sharp-pointed scalpel and gum lancet; (4) probe, director, and exploring needle; (5) needles, ligatures, &c.; and (6) thermometer. The instruments are tools, not toys, being four inches long. The case can be carried in the watch pocket as constantly and with as little consciousness of its presence as an ordinary card-case.

T. H. WARD, M.D.

Paignton.

THE CHELTENHAM GENERAL HOSPITAL.—The annual meeting of the subscribers of the Cheltenham General Hospital was held on March 18th, under the presidency of Colonel Croker-King. The report showed that during 1895 the out-patients had numbered 4176, being 281 in excess of those of the previous year, and 997 in-patients had been treated, an increase of 104 compared with the number in 1894. The average daily number of in-patients was 59. The total expenses amounted to £5687, being £951 in excess of the income.

THE LANCET.

LONDON: SATURDAY, APRIL 11, 1896.

THE report issued last week by the Metropolitan Asylums Board on the results from the use of antitoxin in diphtheria shows that during the year 1895 there were 3529 cases of diphtheria treated in these six metropolitan asylum hospitals, of which 796, or 22·5 per cent., proved fatal; in 1894 the number of cases treated was 3042 and the deaths 902, showing a mortality equal to 29·6 per cent. Thus the proportional case-mortality was 7·1 per cent. lower in 1895 than in 1894. This marked decline in the mortality of hospital-treated cases of diphtheria in 1895 naturally suggests an inquiry as to the cause of the decline, and the six medical superintendents, on the ground that the average severity of the cases was, "in their opinion, about equal" in the two years, have arrived at the conclusion that the decline was due to antitoxin treatment in nearly 62 per cent. of the cases in 1895. It is true that the case-mortality of diphtheria cases treated in the Metropolitan Asylum Hospitals in the seven years, 1888–94, did not once fall below 29 per cent., whereas in 1895, when antitoxin treatment was first generally adopted, it fell to 22·5; on the other hand it should be noted that during the seven years referred to above the case-mortality almost continually fell from 50 per cent. in 1888, when the numbers were small, to 29 in 1894 when the maximum number of cases was under treatment. While, therefore, we admit that the reporters were apparently, in the absence of other known cause, justified in attributing the decline of the case-mortality from diphtheria in 1895 to antitoxin treatment, it seems but prudent to recognise the possibility of this decline being partly due to a continuance of the decline that prevailed during the seven years 1888-94 and partly to a decreased severity in the type of the disease in 1895, since it is a fact that the rate of mortality from diphtheria in London, which was 0·76 and 0·63 per 1000 of the population in 1893 and 1894, further declined to 0·53 in 1895. It is, however, undoubtedly true that the decreased proportion of diphtheria case-mortality in these hospitals in 1895 implied the recovery of 250 cases that would have been fatal had the proportional case-mortality been the same as it had been in 1894. We scarcely feel justified, however, in assuming that the whole of this saving of life was due to antitoxin, neither does any satisfactory basis appear to exist for estimating what proportion of these saved lives may be credited to this cause. The report tells us that of the 3529 cases of diphtheria treated in these hospitals in 1895 62 per cent. were treated with antitoxin, and it follows that 38 per cent. were not so treated. It might have been hoped that a comparison of the observed results in these two series of cases would have afforded a satisfactory means for testing the effect of antitoxin on the proportional case-mortality. Unfortunately, however, the carefully prepared and elaborate tables contained in the report are practically useless for this purpose. The report states that (1) antitoxin was only administered in those cases which were severe or in which the symptoms on admission were sufficiently pronounced to give rise to anxiety, and (2) that no antitoxin was administered in those cases in which the patients were moribund at the time of their admission to the hospitals. It is obvious, therefore, that the two series of cases are incomparable. How futile would be any attempt to compare the case-mortality of the cases treated with antitoxin with the case-mortality of those not so treated the following figures conclusively prove. The proportional mortality of the 2182 cases treated in these hospitals in 1895 with antitoxin was equal to 28·1 per cent.; these included, we should repeat, for the most part the severe cases, exclusive of those held to be practically moribund at the time of admission. The remaining 1347 cases, made up it would appear mainly of mild and moribund cases, showed a case mortality of only 13·4 per cent. It is needless to dwell upon such a comparison. It is impossible, however, not to regret that some other statistical method was not devised that would have thrown more light upon the result of the antitoxin treatment of diphtheria cases in these hospitals, and we venture to hope that it may yet be possible to collect and tabulate facts which will be more helpful in this direction than the report that has just been issued.

It is, however, abundantly clear that the introduction of this method of treatment has had a most marked influence in mitigating the severity of the disease, as shown by the unanimous testimony of all the reporters; and it seems also further evident that the influence for good has been proportionate to the degree to which the remedy was pushed and to the promptness of its application. We may refer, in proof of these assertions, to the somewhat striking figures relating to laryngeal diphtheria. In the first place, be it noted that extension of the membrane to the larynx after admission occurred in a much smaller proportion of cases in 1895 than in 1894, bearing out one of the prominent effects of the injection—namely, that of limiting the degree and extent of the membranous exudation. In the year 1894 there were 466 cases of laryngeal diphtheria with a case-mortality of 62 per cent.; in 1895 there were 543 such cases with a mortality of 42·3 per cent. The degree of laryngeal implication may, to a certain extent, be measured by the number subjected to tracheotomy, and we find that in 1894 there were 56 per cent. so treated; in 1895 there were 45·3 per cent. Again, the proportion of fatal cases after tracheotomy was much higher in 1894 than in 1895; for in 1894 of 261 tracheotomised subjects 164 died, or 70·4 per cent.; in 1895, of 255 tracheotomised subjects 125 died, or 49·4 per cent. There were only 13 of this latter series who did not have antitoxin. This marked improvement in the results of tracheotomy was observed at each of the hospitals, and cannot be ascribed to any accidental circumstance. The medical superintendents further report a general amelioration of the condition of the patients subjected to the antitoxin treatment, noting, among other things, that even in cases which proved ultimately fatal life was more prolonged in those so treated in each of the hospitals except one, and that one where the dose of antitoxin given was on an average much lower than that given at the other hospitals.

On the other hand, there seems to have been a larger

Digitized by Google

proportion of complications (notably albuminuria and paralysis) in the cases treated in 1895 as compared with those of 1894, a fact partly explicable, no doubt, by more careful observation, partly also by the greater proportion of recovery of severe cases. Even if it be conceded that albuminuria is more frequent after the use of antitoxin there is no evidence that actual nephritis is more common. Statistics are also given as to the number of cases in which secondary effects—such as rash, joint-pains, &c.—followed the use of antitoxin, but the general consensus is that, in spite of these results of the new treatment, the condition of those so treated contrasted favourably with those formerly observed. The importance of an early recourse to the remedy is shown in a striking manner in the supplementary report on 119 cases of post-scarlatinal diphtheria at the Northern Hospital. Antitoxin was given in 58 cases, with a mortality of 6·9 per cent.; in 12 the treatment was commenced on the first day, none died; in 27 on the second day, 2 died; 8 on the third day, none died; 1 on the fourth day, recovered; 10 on the fifth day and later, 2 deaths. Now as in all like cases occurring in the previous five years the mortality had been as high as 61·9 per cent. it is impossible to avoid the conclusion that so great a difference must be ascribed to the use of the antitoxic serum or to fail to see that as we know more of the dosage and time of its employment the beneficial effects of the remedy will become more and more evident.

IF our voluntary hospital system, with its splendid traditions, is to be preserved it is necessary that its friends should consider how best to compass that most desirable end. None can dispute its claim to the support of all classes of men. We never conceal its liability to abuse or cease to urge precautions against such abuse by shabby persons whose means do not justify their taking gratuitous advice and medicines. But when all allowance on this score has been made the voluntary hospital system of England remains a credit to its humanity that will compare favourably with the State-supported system of foreign countries. If this be true, the best friends of hospitals are those who seek to remedy their faults of administration and distribution, to make them more available for the really poor and more inaccessible to those for whom they were never intended. It is of no use to shut our eyes to the difficulties of such efforts. The hospital is the centre of prodigious forces and of strong interests. Sentiment, charity, science, medical teachers and medical students, the rich and the poor, and all the Churches without distinction of creed gather round them; and all are apt to apply numerical and statistical tests to the prosperity of the particular hospital in which they are most concerned. There has been a tendency of late years even to popularise hospitals and make them attractive. It would be ungracious not to rejoice over every real accommodation and amenity that can brighten the lot of those who are unfortunate enough to need hospitals; but we are of opinion that this is consistent with keeping them in their right place and excluding from them all wrong persons whose diseases and means are such as admit of treatment at home.

We have spoken of the voluntary hospital system. In truth, this word is a little inapplicable. The great danger of the present state of affairs is the want of system. The voluntary principle is an admirable one, but it is jealous of system. It acts locally, impulsively, and irregularly; fails here and succeeds there; it lacks control and organisation and is apt to resent them. Yet these, in truth, are its great defects, by reason of which it comes in often for more criticism than support. If certain needed qualities could be introduced into voluntary hospitals, if they could be brought to regard each other as coöperating for great charitable ends—not merely competing with each other for public subscriptions—if they could be brought to recognise some great common principles of administration, a new era of public confidence and of prosperity would be assured to them. How is this great object to be achieved? Answers to this question differ. The one most generally accepted is, "By the creation of a Central Hospital Board," on which all classes of persons who have shown interest in, or sympathy for, hospitals shall be represented: subscribers, medical officers, the medical profession, the Council of the Hospital Sunday Fund and the Council of the Hospital Saturday Fund. Such a Board was originally suggested by the Charity Organisation Society, and the Committee of the House of Lords on Hospitals adopted the suggestion almost in its entirety. It has been repeatedly urged by the society, and is again to be advocated at a meeting of the Council on April 13th at 4.30 P.M. at the Royal United Service Institution. It must be confessed that there has been no great enthusiasm shown by the public or by the hospitals with regard to this suggestion. Four years have elapsed since a Central Hospital Board was recommended by the Committee of the House of Lords after a searching investigation into the worth of the hospital system, and nothing has been done. The chief explanation of this delay is probably to be found in the jealousy of individual hospitals, particularly of those institutions the *raison d'être* of which is not very demonstrable. It is extremely desirable that those who object to such a Board should reconsider their indifference or their opposition. By such opposition they give enemies of the hospital system reason to believe that they are afraid of the very gentle control operating only through public opinion which such a Board might exercise over obvious faults in the present system, or rather want of system. We cannot think that the true friends of hospitals will be well advised if they longer resist, even by indifference, the proposal for a Central Board. Existing institutions must be accepted and can scarcely fail to benefit from the action of the Board. It would seem to be their obvious interest to combine together for the purpose of strengthening each other and strengthening that public confidence on which the support of hospitals depends. It would be one of the functions of such a Board to discourage the constant multiplication of small and feeble hospitals, which only weaken those already in existence. The constitution of the Board is a detail on which we need not here dilate. There could be no serious difficulty in the general principles to be recognised in its formation. But we impress on all friends of voluntary hospitals that they should give to this proposal most careful consideration. The Board should be formed voluntarily and without the aid of legislation. The glory of the system is the voluntary

Digitized by Google

principle; only let its supporters have the courage to see its weak points and to strengthen them. The Hospital Sunday Fund and the Hospital Saturday Fund might, by adopting a definite course of action, have rendered such a proposal unnecessary. However, their constitution is, perhaps, scarcely wide enough for these functions.

THE articles on questions of public health which periodically appear in the *Times* are of great value; they are very widely read and they deservedly carry great weight. This, however, makes it all the more important that when any such article, by reason of its alleged facts or by reason of the inferences which are certain to be drawn from its dicta, suggests that which is not strictly correct attention should be drawn to the subject and misapprehension on the part of the public be as far as practicable avoided. For this reason we find it desirable to advert to one part of an otherwise extremely interesting leading article which appeared in the *Times* on March 23rd and in which the subject dealt with was the recent Milroy Lectures delivered before the Royal College of Physicians of London. In the latter part of that article the question of the diffusion of small-pox around hospitals in which cases of that disease are aggregated was discussed; and, referring to the report of the Royal Commission on Small-pox Hospitals, 1882, the writer stated that the Commission "could only recommend that small-pox hospitals should be placed as far as might be from other habitations." We are unable to find in the report of the Commission any recommendation which seems quite to this effect, and we rather doubt whether this was the view of the Commission because they did make a definite recommendation which was exactly in the opposite direction. This was to the effect that for "400 or 500" metropolitan small-pox cases wards "might be maintained within the precincts of the fever hospitals sufficient in each hospital for thirty or forty small-pox patients," the then existing fever hospitals being known to lie in near proximity to large numbers of human habitations. And, unfortunately, this recommendation was acted on for a series of years, with the result that the small-pox infection was again diffused to the population around the hospitals, the distribution of the infection being graduated according to proximity to the hospitals in precisely the same way as had been the case before the date of the appointment of the Commission. It was, indeed, only in 1886, and subsequently therefore to the new experience to the effect that no administrative efficiency could prevent this diffusion, that the Metropolitan Asylums Board once and for all gave up the attempt to isolate small-pox anywhere within or near the metropolis.

The article to which we refer went on to say that small-pox hospitals have now been on their trial for a considerable period, and that "the mischief, if any, which they have occasioned has been of infinitely smaller amount than that which they have prevented." Clearly provincial small-pox hospitals are not here in question; otherwise such cases as the outbursts around the small-pox hospitals at Warrington, Sheffield, Leicester, &c., would have led to much more guarded language. The metropolis was in the writer's mind, and limited to the metropolis the statement is absolutely correct. But, unfortunately, the metropolitan experience has really no bearing on the subject, for the experience of London since 1886 is concerned with the almost entire absence of any small-pox hospitals, these institutions having been relegated to the provinces, where they were placed at a distance of some twenty miles from the metropolis. Under these circumstances it is very natural that London should have benefited in the matter. But the altogether altered circumstances of London since 1886 do not seem to have been apprehended, for the article goes on to refer to the metropolitan experience of small-pox during the past ten years and to say that "the small-pox which has arisen spontaneously and that which has been disseminated from the hospitals, taken together," has been only one-thirtieth of that which arose spontaneously before the hospitals were established. The statistics are of course correct in so far as the metropolis is concerned; but they have no application to the question under review. For the past ten years referred to the small-pox hospitals of the Metropolitan Asylums Board, as already explained, have not existed in or near London, and hence there has been no small-pox disseminated by them to add to that which has arisen spontaneously in the metropolis. The application of the statistical argument should have been in precisely the opposite direction, for it goes to show that when small-pox is not disseminated to the metropolis by means of hospital aggregations, then the elimination of this artificial element in the diffusion of the disease leads to an enormous diminution in our London small-pox mortality.

This view receives confirmation from the fact that in the provinces where it has not been possible to place small-pox hospitals twenty miles away from the communities using them there has been nothing like the same reduction in the rate of the small-pox mortality; the provincial rate for the same period has, indeed, only been one-fourth, instead of one-thirtieth, of that which it formerly was, and one reason for the lessened rate has been the recurring provincial experience to the effect that where authorities persist in placing small-pox hospitals within or near the borders of their sanitary areas they have again and again had outbursts of small-pox in their communities. It is also noteworthy that these outbursts have rarely been in the poorest and most densely peopled parts of the boroughs or towns concerned, but in the localities which were nearest to the small-pox hospitals.

THE report of the departmental committee, which was appointed in September, 1894, to inquire into the prevailing systems for the maintenance and administration of Poor-law schools in so far as the metropolitan area is concerned, has just been issued, and at a time when the attention of Parliament is directed to the Education Bill now on the table of the House. Its appearance is therefore opportune, seeing that it touches directly, *inter alia*, on the important matter of the education of the inmates of Poor-law institutions in a manner which happily accords with the proposed measure now before Parliament. To sum up the report of the committee in one sentence would be to say that the representative body of experts which constitute it

Digitized by Google

have arrived at a very definite conclusion as to the practical failure of Poor-law schools to meet the necessities of pauper infant life as they are seen to arise, and that they propose to bring about the requisite amelioration of the present condition of affairs by relegating to a central and newly constituted body the powers now exercised by central and local authorities—to wit, the Local Government Board and boards of guardians throughout London.

That the recommendations of the committee will have great weight we do not question, coming as they do from persons of acknowledged authority. We have only to look at the names to feel assured of this. The report is signed by the chairman, Mr. MUNDELLA, by Sir JOHN GORST, Mr. LYULPH STANLEY, the Rev. BROOKE LAMBERT, Mr. VALLANCE, Mrs. BARNETT, Mr. NETTLESHIP, F.R.C.S., and Dr. J. G. FITCH, lately chief inspector of schools under the Education Department, names which vouch for the trustworthiness of the document. We are told of fifty meetings, of seventy-three witnesses examined (including Government inspectors, guardians, school teachers, medical officers, and philanthropic experts), and of surprise visits paid by the committee here and there for the purpose of testing the normal working of the school system in individual parishes. In these and in other ways we are assured of the thoroughness of the work detailed in the report. All these facts add weight to the conclusions arrived at. Briefly, it is seen that the "barrack school" system inaugurated fifty years ago, real as was the advance made by the system at the time of its conception, has failed in many respects to recommend itself to the majority of those connected with the work. The medical witnesses have been unanimous in condemnation of the system, not only on the ground of its direct bearing on the health of the children, especially as regards the ever prevailing ophthalmic cases, but also indirectly by reason of the tendency to affect injuriously the mental, moral, and physical growth of those who have been confined to the monotonous round of the school curriculum. Not only on the youthful and involuntary inmates has this effect been noticeable, but officers and teachers have felt in large degree the dull monotony of the surroundings to which they have been more or less restricted. The depression that has resulted has had undoubted effect on the capacity of the children to act the part which is played by their colleagues placed in happier circumstances, and alike in play, in scholastic attainments, in the learning of trades or the exercise of domestic duties the school system has been abundantly proved to have had a baneful effect on those compelled to undergo its ceaseless round. Ophthalmia has become endemic despite every effort to eradicate it, and ringworm and skin complaints in general have been handed on from child to child until the sufferer chanced to be placed in one of the scattered homes, or, better still, boarded out. It is, in fact, this alternative system of "boarding out" of children in the cottage homes of reputable folk that the committee recommend as likely in a large degree to check the evils attendant on the barrack school principle. It has been demonstrated again and again, even apart altogether from the evidence adduced before the committee, that the boarding out of children has had the most beneficial results, both as regards health, physical development, capacity to grasp and retain the teachings of school life, and general mental culture. The children have by this means been removed from the association of pauper existence and have been placed in a position from which they have been grafted into the general social system fitted to their station, and have thus escaped the pauper taint which has militated to such a marked extent against the future chances of their less fortunate fellows.

We do not here touch on the educational phase of the matter, important as it is, nor do we treat of the financial aspects of the question save to state that the results of scattered homes and of boarding out are in favour of the economists; neither have we space in which to set forth the statements of the committee on such points as half-time employment, apprenticeship, and the like. We can only now refer to the specific recommendations at the end of the report. These desire the establishment of a centrally constituted body having full financial and general control of all the London institutions for Poor-law children, with a common expenses fund; the total exclusion of all children over three years of age from the association of workhouses; the gradual abandonment and immediate reduction in scope of the large school system, with increase of scattered homes, and especially an extension of the boarding-out system; the establishment of certified homes, of ophthalmic and other hospital schools, with uninterrupted education of their inmates; the special treatment of the feeble-minded in houses and voluntary homes; the provision of special schools for the tending of vagrant children; improved industrial training; the provision of training ships; the encouragement of emigration; and the appointment of an adequate inspectorial staff, including medically qualified women inspectors. In these and other ways the committee would hope to see the very desirable end accomplished of dissociating the children from pauper surroundings, so that they might take their place in the world untrammelled by their antecedents.

Annotations.

"Ne quid nimis."

THE REMUNERATION OF MEDICAL WITNESSES.

A REQUEST was sent on March 12th to Sir Matthew White Ridley, the Home Secretary, asking him to receive a deputation from the United Kingdom Police Surgeons' Association. Their wish was to confer with Sir Matthew White Ridley on two points: (1) the appointment of police surgeons in districts where none had as yet been made; and (2) the desirability of revising and increasing the scale of fees now awarded to medical witnesses in the police, sessions', and assize courts. Sir Matthew White Ridley has declined to receive the deputation on the grounds that he has already drawn the attention of such police authorities as have not yet appointed police surgeons to the desirability of doing so. With reference to the second point he observed that being fully in possession of the views of the Association he does not think it would serve any useful purpose for him to receive a deputation to discuss it further. The Home Secretary's decision is, we think, to be regretted. Since the reception of the last deputation

Digitized by Google

from this association by Mr. Asquith many assizes and sessions have been held bringing with them additional hardships upon police surgeons and other medical witnesses. Mr. Asquith freely admitted that the scale of fees framed by Sir George Grey many years ago and fixing the remuneration of medical witnesses in the sessions' and assize courts at £1 1s. per day was not an adequate one for the loss of time incurred by professional gentlemen. But he naïvely added that all his predecessors in office, although repeatedly appealed to on the subject, had declined the responsibility of revising the scale of fees and that he felt no disposition to burn his fingers. Evidently Sir Matthew White Ridley feels no more desire to go through the finger-burning process than any of his predecessors. But how much longer is this injustice to members of an honourable profession to continue? The duties of medical witnesses for the prosecution of offenders against the law are sufficiently onerous and are attended with inconveniences enough without the additional injustice of not being remunerated at all or even of being actually out of pocket. That this is no exaggeration has been repeatedly shown in THE LANCET and will probably appear again. In Scotland medical witnesses receive two guineas for each day they are cited to appear in the circuit court of the town in which they are residing and three guineas if the court is held at a distance. There are also, we believe, allowances for travelling and other expenses. Very different is the scale of fees and allowances in England and Wales. However distant the assize town or city may be the fee is the same—one guinea per diem, one railway fare there and back (not always first class), and two shillings per night! Even this last item, which was a positive insult to professional gentlemen, has, we are informed, been discontinued. We would urge all medical witnesses, whether they be police surgeons or not, to send full details of their most recent experiences at assizes, especially at a distance from their own homes, showing, on the one hand, the expenses they were compelled to incur during their absence from home, including the services of a locum-tenent, and, on the other hand, the exact amount of the inadequate remuneration they received. Members of the medical profession are proverbially long-suffering, especially on the subject of fees, but there is a limit even to their endurance and there are manifest indications that this limit has now been reached. If the authorities in England and Wales decline to remunerate medical witnesses with at least some approach to a reasonable acknowledgment of the value of their services they must not be surprised if the duties of medical witness for the Crown come to be declined by many who now undertake them.

THE PERILS OF PRACTICE.

AT the Liverpool Assizes, on March 17th, a claim was made against a medical man named Wright, practising in Wigan, for £250 damages for injuries to the plaintiff arising from his alleged negligence as a medical man. The case was heard by Mr. Justice Vaughan Williams and a special jury. The plaintiff was a club patient of the defendant, and at 5 A.M. on May 1st, 1895, was taken to his surgery with a contused wound of the right hand, in which the tissues were lacerated to the bone longitudinally over the fourth metacarpal bone for about two inches. The defendant took great pains with the treatment so as to prevent cellulitis, and the hand progressed well, but owing to some contraction of the tendons the patient's mother wished him to see another medical man. On May 31st he consulted Mr. Mitchell Roocroft, who told the patient, so the plaintiff and his witnesses said, that the bone in the hand was broken or had been broken and he would require to give him chloroform and refracture it and put it right. Mr. Roocroft treated it till early in July, when he thought the plaintiff was fit for work. The operation which the defendant proposed to perform was to break down the adhesions, but he denied that there had ever been any fracture. The hand was now a success so far as it could be after such a wound, but the action arose from the alleged negligence in failing to discover the fracture. The defence was that there never was a fracture, therefore there was no negligence. The case appeared to rest for some time on the statements of the plaintiff and his witnesses as to what this medical man said and what the defendant said in reference to the injury. Mr. Southam, surgeon to the Manchester Royal Infirmary; Mr. Robert Jones, surgeon to the Liverpool Royal Southern Hospital; Mr. Berry, senior surgeon to the Royal Albert Edward Infirmary, Wigan; and Dr. Robert Prosser White, also surgeon to the Royal Albert Edward Infirmary, all testified to the fact that there was no evidence now of there ever having been a fracture, Mr. Jones telling the jury he had never seen a fracture specimen in a museum in which some evidence had not been left of its having been a fracture. The plaintiff's advocate stated in opening the case that they could not afford to pay for medical evidence. Later, however, he announced that Mr. Roocroft was present, and the judge and jury wishing to hear him the defendant's counsel consented that he should go into the box. He stated that he found an ununited fracture, and he broke down adhesions and placed it on a splint for two or three weeks. He handed a notebook to the judge which contained notes of the case, which the judge read, and after the address of the counsel for the plaintiff he asked Mr. Roocroft when he made the entries in his book, and Mr. Roocroft replied that they were made about a week or two ago from his notes taken at the time, but his lordship observed he should like to have seen the original notes. His lordship, in summing up to the jury, said it was a very interesting case, and made the humorous remark that fortunately before he was made a judge he belonged to a profession and whether he was negligent or not no action could be brought against him. He told the jury they could decide the case without deciding whether there was a fracture or not. The question was whether the defendant treated the case skilfully and whether they were satisfied on the medical evidence that the medical man was guilty of negligence. The jury, without leaving the box, found for the defendant. This case is a very important one and shows the risks run in surgical practice. We sympathise with Mr. Wright in the annoyance and anxiety he has suffered and congratulate him on his successful defence of the action.

THE REPRESENTATION OF EDINBURGH AND ST. ANDREW'S UNIVERSITIES IN PARLIAMENT.

WE understand that owing to the coming elevation of Sir Charles Pearson to the Bench a vacancy will occur in the Parliamentary representation of the Universities of Edinburgh and St. Andrew's. The tongue of rumour has been busy with the name of Sir James Crichton Browne as a candidate for the seat, but we are able to state with certainty that he will not offer himself for election. Strong efforts will, we believe, be made to secure the seat for Mr. Dickson, who, it is probable, will be the next Solicitor-General for Scotland. The representation has been practically confined of late years to members of the legal profession; in fact, three gentlemen holding the office of Solicitor-General have in succession represented the Universities. In the case of the representation of a university in Parliament it is, we think, a thousand pities that mere politics or party considerations should prevail. A university consists of men of science and learning in various faculties, and it is only fair that no one faculty should monopolise the privilege of sending a representative of the whole university to Parliament. There can surely be little difficulty in finding

Digitized by Google

amongst the graduates of the distinguished Universities of Edinburgh and St. Andrew's a man of medicine or a man of science who would do honour to the representation of his Alma Mater. Among medical graduates mention has been made of Sir William Priestley, M.D., as a candidate, while as a man of science Mr. John Murray, LL.D., whose scientific investigations in connexion with the *Challenger* Expedition are known and appreciated all over the world, has been suggested. We echo what is we know the feeling of a large body of the graduates in expressing the hope that the link which has so long bound the representation of the Universities to a government office will on this occasion be broken; and we are in a position to state that Sir William Priestley is willing to accede to the request that he should allow himself to be nominated for the seat. His election would make no change in the balance of parties.

HEALTH IN THE POST OFFICE SERVICE.

UNDER this heading[1] we recently commented on the unsatisfactory nature of the statistical information supplied by the Post Office officials relative to mortality statistics in connexion with the Departmental Committee which has been inquiring into Post Office matters. We first called attention to the matter on Aug. 31st, 1895, and it is regrettable that nothing should have been since done to make the statistics more reliable. We sincerely trust, therefore, that a resolution which is to be proposed at the Annual Conference of the Postal Telegraph Clerks' Association at Exeter on May 29th next will be passed unanimously and that the authorities will lose no time in carrying out its recommendations. The resolution runs as follows:—

"This Conference expresses its regret that the immense and invaluable opportunities afforded for the collection of reliable statistical information relating to many important questions in economic science and public health which are afforded by the large bodies of men and women employed by the Post Office are not utilised, and urges upon the Postmaster-General the desirability of taking steps towards the collection and periodical publication of statistical information relating to postal employés, which shall be easily accessible and readily comparable with the statistical information now collected and tabulated by the Board of Trade, the Registrar-General's, and other public departments."

STREET NOISES.

AN American journal recently published a cartoon representing an Italian organ-grinder plying his itinerant vocation in Africa with King Menelek flying in the distance from the discordant strain of "Sweet Marie," and underneath the legend, "The Italians should have stuck to their regular weapons." This is, perhaps, too ridiculous, but it, at any rate, shows an intelligent appreciation of one class of hideous noise with which civilised nations are afflicted. The enormity of the evil has now become so great that hardly a day passes without some long-sufferer writing to the daily press to complain of his torture. A Bill, to which we have previously alluded, is now before Parliament, but a few such cases as that which was heard at the Thames Police Court on March 31st last will do much to stop the nuisance in the meantime. A restaurant keeper requested a man who was "playing" an organ a short distance from his restaurant to "go away," and on his refusing to do so gave the man into custody. Mr. Mead, before whom the man was brought, imposed a fine of 10*s.* or in the alternative committal for seven days with hard labour. In the course of his remarks Mr. Mead said he quite appreciated the justice of the complaint and expressed his willingness to do all he could to help the prosecutor and others in the matter. The particular section which dealt with street music was not the only remedy for dealing with the nuisance, as persons could be prosecuted for creating an obstruction. If any one person was annoyed by an organ playing he had a right to interfere. The same remarks applied to the Salvation Army, who could be summoned if they refused to go away. The applicant thanked the magistrate for his advice, and remarked that he might have occasion to trouble Mr. Mead again. We hope he will should the nuisance be continued. Mr. Charles Fox of 104, Ritherdon-road, S.W., the honorary secretary of the Association for the Suppression of Street Noises, is collecting evidence as to the baneful effects of street noises on the patients of medical men, and we shall be glad to hear from any of our readers who can speak of the harmful effects of such noises on their patients.

CONTAGION FROM KISSING.

IF there is one thing more than another calculated to rouse the funny man of the lay press it is the mere idea of the suppression or regulation of osculation from its undoubted capabilities as a medium for the spread of contagious disease. Dr. Coleman, reporting as to the health of Surbiton, states that he has not been able to find an atom of evidence of local defects of sanitation to account for certain cases of fever, and goes on to refer to the danger of "slight" cases of diphtheria, for, as he says, being so mild they are not always treated with the extreme care that experience warns us that such attacks when mild require. Many cases, he points out, are not recognised; no medical man is called in and the individual meanwhile by personal contact is capable of spreading the disease; and of all means the most personal and at the same time the most natural and probable is kissing. It should be a rule, he says, in all houses to never let a child or grown-up person with a sore throat, no matter what it may be called or be supposed to be, kiss or be kissed by another. He also suggests obvious precautions as regards spoons, cups, and such-like articles.

SHEFFIELD AND ITS HEALTH OFFICER.

WE recently commented[1] on the action of the city council of Sheffield in refusing to endorse the recommendation of its Health Committee to raise the salary of the medical officer of health, Dr. Harvey Littlejohn, from £500 to £750 by annual increments of £50. For so important a city as Sheffield this emolument of £500 a year is felt by all who appreciate the services which Dr. Littlejohn has rendered to the city to be totally inadequate. Whatever may be the feeling of the inhabitants in regard to the matter—and we do not think it is the feeling reflected in the action of the council—the medical profession in Sheffield is practically unanimous in the opinion that Dr. Littlejohn's salary should be increased. This has been shown in an effective manner by the presentation of a memorial signed by more than a hundred local practitioners, among them being Mr. Wm. F. Favell, J.P., consulting surgeon to the Sheffield General Infirmary and president of the Sheffield School of Medicine; Dr. William S. Porter, president of the Sheffield Medico-Chirurgical Society and honorary physician to the Sheffield General Infirmary; Mr. James H. Keeling, senior surgeon to the Jessop Hospital and consulting surgeon to the Sheffield Royal Hospital; Dr. Wm. Dyson, senior physician to the Sheffield General Infirmary and consulting physician to the Sheffield Royal Hospital; Mr. Simeon Snell, ophthalmic surgeon to the Sheffield General Infirmary; and Dr. W. T. Cocking, physician to the Sheffield General Infirmary. They also entertained Dr. Littlejohn at dinner at the Victoria Hotel. In a letter read from Mr. William F. Favell occurs the passage, "A first-rate medical officer of health is a great

[1] THE LANCET, Feb. 29th, 1896.

[1] THE LANCET, Feb. 22nd, 1896, p. 502.

Digitized by Google

power for good in a community such as ours, and an incompetent one a great power for evil." It is needless to comment on this passage, and the memorial, excerpts from which we append, speaks for itself:—

"MEMORIAL.

"Sheffield, February, 1896.

"DEAR DR. LITTLEJOHN,—We, the undersigned members of your profession, resident in Sheffield and the vicinity, have observed with regret the refusal of the city council to grant an increase of your stipend. ..... If the services of a competent officer are to be retained it will, in our opinion, be necessary to raise the remuneration attached to the office of medical officer so as to bring it more in accord with that found in other important towns in the kingdom, and which shall bear a better relative proportion to the (by no means more important) positions held by other city officials. ..... The notification of diseases, which is so liable to occasion friction, has been carried out by you with such courtesy towards your professional brethren that not only has the city been a gainer, but your relations to your *confrères* have been most cordial and harmonious."

TETANY TREATED BY THYROID EXTRACT.

IN a recent number of the *Archives of Pediatrics* Dr. John Thomson of Edinburgh records a case of tetany in a rickety child fifteen months old who was treated unsuccessfully with thyroid. The condition of tetany had become established four days before the child was seen, and Dr. Thomson was induced to try the thyroid extract from remembering the frequency with which tetany has been said to occur in cases in which the thyroid gland has been excised. No change was made in the diet for some days and thyroid tabloids were given. The child, however, continued steadily to get worse, but rapid improvement took place when a suitable dietary was instituted. Dr. Thomson alludes to the remarkable results obtained by thyroid treatment by Dr. Bramwell and also by Dr. Gottstein and he points out that there are probably very essential differences between the idiopathic tetany of adults and the commoner form in children so frequently, if not invariably, associated with rickets. Yet from the similarity of the symptoms it might be expected that what was beneficial in one would be beneficial in the other. Dr. Thomson's case, however, does not indicate this, although it must be confessed that the trial was not quite a conclusive one.

TAKING THE OATH.

AMONG the many reforms relating to the health of the public which THE LANCET has strenuously advocated the question of swearing with the uplifted hand has occupied a prominent place. It is a question of momentous importance to every person who has to enter the witness box, inasmuch as on it may depend the health not only of themselves but of everyone who is near and dear to them. To recapitulate the arguments which have been brought forward and the proofs which have been given to demonstrate the evils which may arise from the form in which the oath is generally administered in English courts is unnecessary, as we have done so repeatedly, but the following piece of testimony, which we extract from a paper on the Administration of Oaths in British Courts of Law and elsewhere in Great Britain, read before a recent General Chapter of the Guild of St. Luke by Mr. Frederick Lowndes, and printed in the Monthly Paper of the Guild for March, should be attentively perused by all whose duty involves the necessity of taking the oath. Says Mr. Lowndes:—

"Personally, nothing can be more distasteful to me than to appear singular or different from other witnesses, whether they be or not my professional brethren. Let me give briefly my reasons and my experiences. Nearly twelve years ago I gave evidence at the police-court before the grand jury and in the Crown Court, the case being one of rape. The first witness, a girl aged fourteen, was suffering from constitutional syphilis, and all the other witnesses, myself included, were sworn on the same Testament. Again, since that date I have had to appear as a witness very frequently—on one occasion five times in one day. For the reasons I have already given I must, on grounds other than those which may be called sanitary, prefer the Scotch oath."

Will not such testimony as this break down the bias of the judges and magistrates who stand in the way of a necessary reform? We have raised our voice again and again against the practice of kissing the book, and there must be but few of the general public who do not know that they need not kiss the book when taking the oath. At the end of January last it gave us pleasure to refer to the praiseworthy example of his Honour Judge Emden, who had notices posted up in his county court calling attention to the fact that the book need not be kissed when taking an oath. The officers of the court were also instructed to tell witnesses when being sworn that they need not kiss the book unless they liked. Who among our officers of the law will follow his example

THE CHALYBEATE WATER OF HAARLEM.

HAARLEM, the Dutch city famous among many other things for the great organ in the cathedral and known everywhere for the cultivation and exportation of tulips and other flowering bulbs, possesses a chalybeate spring which promises to give that part of Holland a reputation as a health resort. It is stated that iron is present in the water in a large, though not excessive, amount, each litre containing 11 centigrammes of oxide (= about 7 grains per gallon) as well as 3·24 grammes of sodium chloride and a small proportion of manganese. The temperature of the spring is 11° C. (= 51·8° F.). It has been named the Wilhelmina Bron, no doubt after the youthful Queen of Holland. A handsome pump-room has been erected, and there is a bathing establishment in which chalybeate baths at any temperature, with or without the addition of carbonic acid, may be had. There are also rooms for sulphur baths, salt baths, mud baths, douche baths in all possible forms, vapour baths, and a gymnastic department with appliances for every kind of exercise. A description of these necessary adjuncts has been written in English by Dr. C. E. Daniels of Amsterdam, who adds numerous medical testimonials as to the utility of the water and its non-liability to produce constipation. Haarlem is a city of about 59,000 inhabitants, and it is, of course, very easy of access.

OUR ROADS.

SOME eighteen hundred years have passed since our forefathers were taught the art of road-making by the armies of Cæsar, and it might have been thought that this period was sufficiently long for evolution to have produced the most perfect type of *via*. Unfortunately this is not so, as all who travel much on our great highways (and notably medical practitioners) must know, and we agree with the author of a pamphlet issued by the Roads Improvement Association when he says "we as a nation have failed to keep abreast of the times, while our neighbours across the Channel ..... give us a long start." No doubt the advent of railroads has much to answer for as regards our apathy in this respect, but good roads are a fundamental necessity for a country like England, which owes not a little of its greatness to the arteries of commerce commenced by the Romans and recorded in the "Itinerary of Antoninus." With the advent of the horseless carriage the roads of England are likely to prove of even greater importance in the future than they have done in the past, and the work of the Roads Improvement Association,

Digitized by Google

whose address is 57, Basinghall-street, deserves encouragement. The Association is doing good work by directing the attention of the various surveyors and other highway officials throughout England and Wales to the system of road-making and repairing advocated by the Association, which appears to be much appreciated not only by the public in general and by cyclists in particular, but by the various authorities who have charge of our highways and who in many instances have adopted its principles and circulated its instructions amongst their men. Although the services of the committee of the Association and those of its secretary are given voluntarily the expenses attaching to the distribution of a large quantity of literature are necessarily great, and the support of the public is needed.

THE SMALL-POX OBJECT LESSON AT GLOUCESTER.

APPEALING for donations in aid of the small-pox stricken community at Gloucester the Very Reverend H. D. Spence, the Dean of that city, in a letter to the *Times*, concludes with the following remarks: "If the serious object-lesson which Gloucester now presents be laid to heart by those cities of England who are content to rest upon the dilatory proceedings of the Commission on Vaccination appointed some seven years ago, and in consequence are neglecting the one precaution, vaccination, which it has been proved by overwhelming evidence can alone save our people from the horrors of this fatal malady, the sufferers for whom we plead so earnestly will not have suffered in vain." These are words of wisdom, and we hope that the cities referred to will no longer delay the enforcement of the one prophylactic which can prevent epidemics of the deadly scourge.

A CENSUS FOR EGYPT.

ALTHOUGH it is quite true that the reform record in Egypt is, as Lord Cromer puts it, one of "steady and unostentatious progress," there are, nevertheless, some matters to which we venture to think a sufficiency of attention has not as yet been directed. In the first place it is absolutely necessary that an accurate census of the people should forthwith be established. This very elementary step towards civilisation should have been taken long since; but, on the principle of better late than never, we trust that no more time will now be lost. The sanitary department makes laudable efforts to furnish vital statistics, but for lack of a reliable basis to work on the results are shorn of half their value. There is not a civilised State in the world in which the rulers do not regard a correct census as a matter of the utmost importance, and it little becomes Englishmen to allow the country they are reforming to be behindhand in this respect. In Egypt the cost of a census would not be great, for a good deal of the machinery is already in existence, and the Sheikhs and Omdehs are said to be thoroughly alive to the beneficent intentions towards them of their English controllers. Now that the finances of Egypt are so marvellously prosperous it is surely not unreasonable to ask, in the interests of hygiene and demography, that steps should be immediately taken to establish a trustworthy census throughout the country.

VAGRANTS.

THE part played in the dissemination of infectious disease by persons of the vagrant class and particularly just now the interest centred in the West of England and South Wales by reason of an extending small-pox outburst render the issue of the latest Parliamentary return of the numbers of vagrants relieved in England and Wales more than usually important. As compared with the first day of 1891 the vagrants relieved in the several unions on Jan. 1st, 1895, showed an increase of from 4960 to 8810. These numbers were made up of 4204 adult males, 553 adult females, and 164 children under sixteen years of age in 1891; and of 7631, 879, and 297 respectively in 1895. Speaking of proportions, the adult females have not largely increased their numbers, but the disparity between them and the males in actual amount remains enormous and has continued to be increasingly great. In London the aggregate of 754 vagrants relieved in 1891 has grown to 1211, and in the groups of counties comprised in the South Midland, West Midland, North Midland, and Welsh divisions the totals have more than doubled themselves in the four years. Taking as an example the county of Gloucester, where small-pox now rages, we find that on the first day of each successive half-year since January, 1893, the vagrants relieved have been 69, 134, 134, 56, and on Jan. 1st, 1895, as many as 146. This increase, however, has no relation to the vagrants treated in the city workhouse, which on the latter date were only 3 in number. Increases in Yorkshire and the counties still further north have been relatively small.

INTERESTING GIFT TO THE BRITISH MUSEUM.

MR. E. WHEELER, a druggist of Clifton, has recently presented to the British Museum an accurate and scientific register of the actual form and colouring of 2500 of the 3000 specimens of fungi which occur in the British Isles. The work is the labour of many years and consists of twelve volumes of water colour drawings. In acknowledging this handsome gift Professor Flower says: "The trustees desire me to assure you of their high appreciation of the extreme accuracy and beauty with which you have delineated the character of the originals, and to return you their cordial thanks for so munificent a donation to the national collection of natural history."

THE RECENT OUTBREAK OF ILLNESS AT TWYFORD SCHOOL.

DR. FREDERICK W. ANDREWES, in his report on the recent epidemic of sore-throat at Twyford School, gives it as his opinion that the outbreak depended solely on the introduction of diphtheritic poison from outside the school, and that its spread was not affected in any way by lack of proper sanitation. His investigations show that the ventilation, water-supply, and milk-supply were and are most satisfactory. The drainage in a few minor instances might be improved.

THE next annual meeting of the Medico-Psychological Association of Great Britain and Ireland will be held in London, at the rooms of the association, 11, Chandos-street, Cavendish-square, W., in the latter part of July. Notice of the dates and other particulars will be issued in due course, and the council confidently hope that a large gathering of members will be present to show their interest in the work of the association, to read papers, and to take part in the discussions.

THE Huxley Memorial Committee will strike a medal, among other purposes, for award by the Royal College of Science, London. The committee desire designs for this, and particulars will be furnished by the honorary secretary of the Huxley Memorial Committee, Professor G. B. Howes, Royal College of Science, South Kensington, S.W.

THE next meeting of the Odontological Society of Great Britain will be held on Monday evening next, at eight o'clock, when papers will be read by Mr. A. Marmaduke Sheild, Mr. Storer Bennett, and Mr. Charles Tomes, F.R.S.

MR. CHAPLIN, President of the Local Government Board,

Digitized by Google

will receive a deputation from the Workhouse Infirmary Nursing Association on Wednesday next, April 15th, at 2.30 P.M., at the House of Commons.

THE Prince of Wales has fixed Wednesday, June 10th, for the festival dinner at which he will preside at the Imperial Institute in aid of the re-endowment of Guy's Hospital.

ON THE ORIGIN AND HISTORY OF SOME DISEASE-NAMES.

BY WILLIAM SYKES, M.D. DUNELM., F.S.A.,
A CORRESPONDENT OF THE NEW ENGLISH DICTIONARY.

WHILE the New English Dictionary is working out in an exhaustive manner, and on historical lines, the origin, development, and use of every word in the English language, it will not be amiss for members of the medical profession to review their own terminology, both as a small contribution to this monumental work and as an independent attempt to discover the principles on which certain medical terms have come into existence originally. This, again, may not be without use in settling the lines on which they may be most usefully formed and developed in the future. Our vocabulary must, in the first instance, be sought out in the medical literature of all ages: not in the systems of nosology which have been so abundantly produced from the time of Cullen to the present day. The language of a profession is formed from the words actually spoken, written, and read by its members, just as the language of a country consists of the words used and understood by the people, not of the inventions, suggestions, emendations, and alterations of a few scholars in their studies. The subject, indeed, under consideration is the vocabulary of the science of medicine as employed by English writers in English medical works. One cannot help noticing in the first place that, however much Latinised or Grecised the names of diseases may have been in the past, medicine has really collected her vocabulary out of every language under heaven and from every age. Folk-speech dealing with rough objective symptoms has given us no mean proportion of our disease names, folk-adaptation from neighbouring peoples many more, folk-degradation of the language of the learned a few, while the deliberate coinage of writers has of course added largely to the list. In many instances we are able to trace the history of a medical word from its first inception and to decide at once to which of the above classes it belongs; in others we can even name the original birthplace of a word, say from what language it has been adopted, and give almost the exact date of its actual employment in our literature, yet at the same time be unable to perceive the reason of its adoption. The word "scarlatina" is an example of this difficulty. We believe the term to have been first used in English medical literature by the great Sydenham in his "Observationes Medicarum," published in 1676.[1] We also know that the word is of Italian origin, having been actually employed by an Italian writer in 1527,[2] and that it is derived from the Italian "*scarlatto*" (scarlet) in allusion to the colour of the patient's skin; but why Sydenham, who, with the doubtful exception of a period of study at Montpellier, had never been abroad, should have inserted an Italian name amidst a Latin list of maladies is difficult to explain; indeed, we have little to offer beyond conjecture. Could Sydenham's friend, John Locke the philosopher, having seen a case of the disease in his company, have suggested to him the name bestowed upon such abroad? We know that Locke was at Montpellier about the time of the publication of this very work, and we also learn from one of Sydenham's letters[3] that Locke "had troubled himself in visiting with Sydenham very many of his variolous patients especially." May it have been in some communication from him at Montpellier, or elsewhere abroad, that Sydenham received an account of the malady with its name? We know, however, from that quaint but most excellent writer, James Cooke of Warwick, that the English term "scarlet fever" as applied to this very disease was in provincial use in Sydenham's own time. The first edition of Cooke's "Mellificium Chirurgiæ, or Marrow of Surgery," preceded that of Sydenham's "Observationes Medicarum" by a year, while its fourth edition, from which I quote, appeared only nine years later. In what edition the passage I extract was first inserted I cannot, in the absence of the earlier editions, at present ascertain. In his fourth edition, however, Cooke describes a disease he calls "rosalia,"[4] as showing "red, fiery spots which break out at the beginning of the disease all over the body, as if it were a small *erysipelas*, though the tumour is hardly discernible." "They sometimes," he continues, "break not forth till the fourth or fifth day; in the progress of the disease they sometimes possess the whole body, so that it looks as though it were all on a red fire, which colour is again changed into spots as at the beginning, which vanish upon the seventh or eighth day, the cuticle falling off in Scales or great Fleaks. The first and last of these [i.e., small-pox and rosalia] were at Warwick," he says, "at the writing hereof, the last going under the name of scarlet fever." It is possible, if Sydenham originally wrote his works in English, as has been stated, and was indebted to Dr. Mapletoft or another hand for his Latin translation, that he used the English term "scarlet fever" and owed the Italian "scarlatina" to his translator. It is at any rate a curious fact, as Dr. Mason Good notices on Dr. Willan's authority,[5] that "scarlatina" was first used by British writers — as indeed has continued to be the case ever since—although Dr. Good remarks[6] that "in saying that the denomination scarlatina was first applied to the disease by British writers Dr. Willan can only mean that it was by British writers first applied *technically* and introduced as a professional term into the medical vocabulary; for the term itself is Italian and was long a vernacular name in use on the shores of the Levant before it was imported into our own country." Be the reason of its adoption what it may, "scarlatina" affords an excellent instance of the uselessness of attempting to supplant a widely-accepted disease-name by some more elegant or scholarly synonym. Dr. Mason Good, in his day a great nosologist and classifier of disease, made a deliberate attempt during the early third of the present century, when his works were in vogue, to replace "scarlatina" by the old term "rosalia." He wrote[7] that "scarlatina is a barbarous and unclassical term, which has unaccountably crept into the nomenclature of medicine upon the proscription of the original and more classical name rosalia," which he states it to be his intention to restore. "It will not," he says, "be the fault of the present author if the correction so universally called for in the case before us should be postponed to another age, or the error complained of be charged upon future nosologists." He goes on to mention De Haen, Morton, Huxham, Heberden, and others as objecting to the use of the term "scarlatina," and, although he mentions Dr. Willan as employing it, he declares that even he considered it necessary to apologise for its continuance on the ground "that, however offensive the term might be to a classical ear, having been first employed by British authors, it could not well be displaced, having obtained admission into all the systems of nosology." Yet, in spite of this consensus of the opinions of great men, we find the word "scarlatina" as commonly used to-day as when Dr. Mason Good wrote, while the suggested amendments of himself and his authors are entirely forgotten in favour of the popular term, which has become so naturalised in our language that its employment is quite as usual as its English equivalent "scarlet fever," which is looked on by the poor as the name of a severer malady, the question being frequently asked whether a patient be suffering from "scarlet fever" or only scarlatina.

Another disease-name of Italian origin is influenza, the exact date of whose introduction into British medical literature is a little uncertain. It was established in both popular and medical use during the epidemic of 1782.[8] Mr. Huxham, who wrote in 1758 an account of the previous epidemic of 1743, says: "This fever seems to have been exactly the same disease as that which in the spring was rife all over Europe,

termed the influenza"; while Dr. George Baker, in describing the immediately preceding epidemic of 1762, writes: "At Norwich ..... according to the testimony of the distinguished physician William Offley ..... a much greater number fell victims than were destroyed by a similar pestilence in 1733 or by the more severe visitation, called influenza, in 1743." Dr. Watson, in a letter to Dr. Huxham dated Dec. 9th, 1762, states that "it is nearly the same disease which was at London in April and May, 1743, and *then called influenza*, the name applied to it in Italy." We may from this evidence assume that the term was first introduced into England during the epidemic of 1743, unless, indeed, Häser's statement, quoted by Dr. Creighton,[9] that the word was used in the title of an Edinburgh graduation thesis in Latin as early as 1703, be more than a clerical error. "Influenza," then, is a term directly imported into England from Italy and imposed on our medical terminology by popular approval. It is not quite plain, however, what the original Italian word indicated in reference to the disease. Zuelzer[10] says that it refers to the assumed influence of the atmosphere or climate, or—from the further signification of the word as something fluid, transient, or fashionable—to a name commonly used in the epidemic of 1709—viz., "die Galantrie-Krankheit" or "das Modefieber."[11] Dr. Creighton, however, remarks[12] that, while the word is usually taken to mean the influence of the stars, and may even have got that sense by popular usage, the original etymology was probably different. He points out that as early as 1554 the Venetian Ambassador in London called the sweating sickness of 1551 an *influsso*, which is the Italian form of *influxio*. The latter is the correct classical term for a humour, catarrh, or defluxion, the Latin *defluxio* itself having now a special limited meaning. It was therefore not astrology, but humoral pathology, that brought in the word *influsso* and *influxio*, out of the former of which word Dr. Creighton suspects that "influenza" grew, rather than out of any notion of influence rained down from the heavenly bodies. All this is, however, little more than conjecture, and can only be set at rest by a resort to Italian literature of the seventeenth and eighteenth centuries, an inquiry conducted on those historical lines which the "New English Dictionary" so well advocates and exemplifies. Curiously enough, the same popular caprice which placed the name "influenza" in the list of specific diseases almost succeeded in finally degrading it into a synonym of a common cold. The great epidemics of the disease in 1833 and 1847 fixed the association of the word so closely in connexion with a catarrhal condition that an influenza cold became an admitted term for an ordinary cold or coryza, especially if attended with sharp fever.[13] It was only the present cycle of outbreak, commencing in 1889, which disassociated the name with any form of catarrh.

In or before 1782 popular favour established the name "la grippe" in as firm a condition of acceptance in France as its rival, "influenza," in England. In this, folk etymology probably assisted. "La grippe" is, according to Joseph Frank,[14] derived from the Polish word *chrypka* (raucedo), but was at once in France referred for its etymology to the French verb *agripper* (to seize), the sudden onset of the attack in those afflicted apparently rendering this derivation a very likely and apt one. A similar instance of transferred derivation took place in the word "dengue," as will be noted directly. Attempts have been made, entirely unsuccessfully, however, to popularise the French *grippe* in England in place of the Italian *influenza*.

With regard to the derivation of the word "dengue," it appears that the term in Spanish means fastidiousness or prudery, also a female dandy; and, as the disease dengue is, on account of neuritic or muscular pain, accompanied by a stiff, ungainly gait and awkward bearing, when it first broke out in Cuba in 1827 no doubt was entertained that its title referred to this peculiarity, as was shown by its immediate translation in the English West Indian possessions into "dandy fever," a name it yet bears. Another popular synonym, "the giraffe," is no doubt referable to the same fact and derivation. Dr. Christie has, however, shown[15] that dengue is really a Swahili word, the full name of the disease in Zanzibar being *ka dinga pepo*, which may be thus construed: *Ka* is a partitive article meaning "a" or "a kind of"; *dinga*, *dyenga*, or *denga* means "a sudden cramp-like seizure"; while *pepo* signifies "an evil spirit or plague." And it was the Swahili *dinga* or *denga* which was confused with the Spanish word *dengue* on the appearance of the disease in the Spanish possessions in 1827. A still more absurd explanation of the meaning of dengue, than the Spanish one in question, has been attempted by some of our own writers. They explain it, by an ingenious method of double beheading, to be nothing more than (A)den (A)gue.

Although the history of the adoption of the French word "diphtheria" in English medical literature, as well as its origin and final alteration, are much better known than that of some of the above terms, yet on account of certain verbal peculiarities which mark its adaptation into English form it is worth recapitulating. In 1821 Brettoneau of Tours read a communication before the then Académie Royale de Médecine on Croup and Malignant Angina, in which the following paragraph occurs[16]: "Let it be permitted me to designate this phlegmasia by the name of *diphthérite*, derived from *διφθέρα, pellis; exuvium, vestis coriacea*." In the same paper the adjective *diphthéritique* also occurs frequently. This new designation for a certain form of croupous inflammation was imported into English medical literature to a somewhat limited extent and in the modified form "diphtheritis." It did not, however, become a part of our terminology and was nearly invariably followed by reference to its French introducers and to French observations. It was accompanied in these instances by its adjective, Englished into "diphtheritic." In 1855 Brettoneau, in a fifth memoir,[17] altered his term *diphthérite* into *diphthérie*. Sir J. R. Cormack[18] asserts that he did this because he had discovered that the disease was not of an inflammatory character. Is it not equally probable that someone had drawn his attention to the fact that his original coinage was made on a mistaken model? It was framed after the example of such words as "iritis," "bronchitis," "laryngitis," &c., where, however, the completed word is composed of two elements, one indicating the region or part affected—e.g., "ir" from "iris" in "iritis"—the other the mark of inflammation, "itis." In Brettoneau's term, however, the primary element of the word dealt with the pellicular result of the inflammation, not at all with the part inflamed. Analysed on the model of the other words ending in *itis*, Brettoneau's coinage resolved itself simply into "the inflammation of a skin or pellicle" instead of into that which he desired to imply—viz., inflammation characterised by the production of a skin or pellicle.

At the same time that Brettoneau, from whatever motive, altered his new substantive from *diphthérite* into *diphthérie* he also amended the adjective *diphthéritique* into the form *diphthérique*. In 1857 a historical epidemic of the disease crossed the Channel from France to England, bringing with it its eagerly adopted French title *diphthérie* in the slightly altered form "diphtheria." Sir J. R. Cormack[19] states "that diphtheria was a word almost unknown in English medical literature till 1859, when the Sydenham Society published a volume of memoirs on the disease," but in this he is quite mistaken; the word made its appearance in the English medical journals as early as 1857, while those of 1858 actually abounded with it, as did the American professional papers for the same year. Its acceptance was widespread and immediate, and it at once became an established member of our language. Not so with the amended form of its adjective *diphthérique*, which a few purists vainly endeavoured to naturalise as "diphtheric." But, with the capriciousness which characterises popular word-adoption, "diphtheric" never became general, and, while Brettoneau's original substantive "diphtheritis" was relegated to the limbo of disused words, its derived adjective, "diphtheritic," was universally adopted in this country, and we have the curious spectacle of a substantive "diphtheria" and a resulting adjective "diphtheritic" which could by no correct method of derivation have been formed from it in a legitimate manner. During the last few months I have noted with some pleasure that a more correctly formed derivative adjective, "diphtherial," has come into vogue, which may, perhaps, in course of time perform that which the equally

correct "diphtheric" could not do—viz., entirely displace the older and incorrect "diphtheritic."

Croup, the name of a disease which is by some thought to be really diphtheria, was transferred during the last century from the Lowland Scottish dialect into a permanent position in our medical nomenclature. In parts of Scotland "to croup" is a verb meaning to cry hoarsely, to croak as a raven, to make a hoarse crowing sound. It appears to be allied in derivation to the English provincial word "roup," applied to a disease of fowls. The verb was also applied to the sound caused in the disease, a use not yet quite obsolete; in some medical works and in many nurseries a child is still said "to croup" when emitting the brassy, harsh cough symptomatic of the complaint. Afterwards, by extension, the term "croup" was doubtless transferred to the disease itself. It was first used in medical literature by Dr. P. Blair,[20] of Cupar, Angus, in 1718, who in describing a hitherto unnoticed malady gave it its local designation. It was not, however, until 1765, when Dr. F. T. Home,[21] another Scotchman, published his treatise on the malady, that it obtained a permanent place in our nosology as a specific disease under its provincial name.

Measles is an old English disease-name which so-called classical nosologists have vainly attempted to replace by such synonyms as "morbilli" and "rubeola." Dr. Creighton[22] says that originally the term "measles" meant the leprous—first in the Latin form *miselli* and *misellæ* (diminutive of *miser*), and that John of Gaddesden, by haphazard bracketing of the disease of measles and the tubercular nodules of leprosy under the common name of "measles," caused the word to be divorced from its original connexion with leprosy and restricted to its common use. "It can," he concludes dogmatically, "hardly be doubted that we owe the English name 'measles' as the equivalent of morbilli to John of Gaddesden." In this, perhaps from taking too exclusively English a standpoint in his examination of the literature of the subject, Dr. Creighton is probably in error. Dr. Skeat,[23] a remarkably accurate writer, declares, on the contrary, that the word "measles" is wholly unconnected with the Middle English *mesel*, a leper, which merely meant originally "a wretch," from the old French *mesel*, Latin *misellus*, the diminutive of *miser*, wretched. Measles is, he says, derived from the Dutch *maseln* (measles); the disease is also called in Holland *masel-sucht*, the measle-sickness, so translated by an old English writer. The literal sense is "small spots." The original word occurs in the Middle High German *mase*, Old High German *masa*, a spot. Hirsch[24] also states that the English word "measles" corresponds to the German *Maal* and *Masern*, and the Sanscrit *masura*, spots: Doubtless it is to this meaning of spots, hence spotty, that we owe the term "measly pork," as applied to the meat of the pig when infested with scolices of tænia.

Of names deliberately invented by medical scholars of set purpose for the designation of diseases or their symptoms some have taken a permanent place in our language and literature, while many more have sunk back into a merited oblivion. Of the former class many were coined to describe diseases or conditions previously unknown, and passed into common acceptation with the recognition of the existence of the maladies they described. Probably "bronchitis" may be taken as an apt illustration of this class. The word was introduced into use by the English Dr. Badham in 1810,[25] and afterwards by the German J. P. Frank in 1812.[26] The disease itself had been hitherto little recognised or investigated under its old name of "peripneumonia notha," so that the alteration in name not only signalised an improvement in both pathology and treatment, but also accompanied a description of disease which familiarised both practitioners and the people with an easily recognisable and striking affection, very common among the poor, and was thus adopted, once and for ever, in the folk-speech of the country.

Other words of this successful class of deliberate scientific coinage have held their ground simply because they were invented to meet the requirements of the learned in regions which, lying beyond the ken or need of the vulgar, were the sole possession of science. The word "aphasia" is an example of this series, the pathological condition it represents being wholly, and the clinical condition nearly, outside the observation and analysis of laymen. Therefore the word was forged by scholars for scholars, after due discussion and alterations, which would have been impossible in the case of a word which was amenable to the disturbing process of public approbation or disapproval.

Trousseau[27] tells us that "the affection now called 'aphasia' was in 1841 termed 'alalia' by Professor Lordat, and that in 1861 M. Broca changed this name for that of 'aphemia.' But M. Chrysaphis, a very distinguished Greek scholar, and himself a Greek, although accepting the term 'alalia,' proposed as a better one that of 'aphasia,' derived from α, privative, and φάσις, speech. M. Littre, whose authority is so great, and M. Briau likewise preferred the word 'aphasia,' and all three concur in rejecting 'aphemia.'" Trousseau himself had at first adopted the name of "aphemia" after M. Broca, but afterwards, on the authority of the scholars named above, substituted for it that of "aphasia." To complete the transaction the German, Küssmaul, has more lately annexed Professor Lordat's discarded word "alalia," and applied it to stammering, an entirely different disease.[28]

One of the most successful and extensive artificial systems of nomenclature in a kindred branch of science was that of Dr. Barclay. In 1803, being then a teacher of anatomy in Edinburgh, he published a new system of anatomical nomenclature, which was so successful that a number of his suggested terms were at once adopted by anatomists and incorporated in their works. Many of them remain in daily use even now. He recommended about twenty-five new adjectives, or adjectives with new meanings, to denote the various aspects and situations of the organs and limbs, &c. His list includes such useful and common words as mesial, lateral, dextral, sinistral, peripheral, central, proximal, and distal.

Thus we see physicians and scholars forging new names as blacksmiths forge horseshoes, but it is, as noted above, only while these new creations are retained in the calmer atmosphere of science that they maintain their vitality. Once let these word-smiths begin making new names for folk maladies, and their artificial creations immediately crumble to pieces before the more robust denizens of the land. It is doubtful, for instance, if Barclay's system of anatomical nomenclature would have so rapidly commended itself if applied to some more popular science. As it was, the moment Barclay transgressed the genius of our language his proposed alterations were ignored and are now forgotten. This was so in the case of his new system of adverbs, of which he suggested a like number with his adjectives. While the latter ended in "al," the former concluded with "ad," and we had "laterad," "dextrad," "sinistrad," and a score or so more of like monstrosities, a very few of which struggled on in very occasional use for about forty years,[29] and are now quite obsolete. Even when scientific coinages have been adopted into the language of the people it is not always certain that men of fair culture correctly analyse them into their original constituents and real signification. In a recent novel of an American author, Frank Stockton,[30] the following sentence occurs: "She was, in a certain sense, a floraphobist, and took an especial delight in finding in foreign countries blossoms which were the same or similar to the flowers she was familiar with in New England." Here the author has evidently formed his word "floraphobist" on some such imaginary model as hydrophobist, derived from hydrophobia, a well-known disease-name handed down to us from Celsus. But unfortunately the result arrived at is entirely opposite in meaning to what the writer intended. "Floraphilist" was the thing

[29] A good résumé of Barclay's nomenclature will be found in Wishart's translation of Scarpa's Treatise on Hernia, Edinburgh, 1814, p. xiii. et seq. The latest anatomical work in which I have noted any instances of Barclay's adverbs is Todd's Cyclopædia of Anatomy and Physiology, 1849, &c. The question has been raised whence was the form ending in "ad" derived—in "centrad," for example. The New English Dictionary suggests it as derived from the Greek κεντρα δε, but the words are entirely Latin in construction, and, were, I doubt not, formed by the displacement of the Latin participle "ad" (to or towards) to the end of the new coined name.

the author desired to indicate, but, evidently confusing in his mind the madness of rabies with the last section of the word "hydrophobia," he took it as tantamount to "mania," and deemed that a "floraphobist" was the same as a "floramaniac"—a somewhat unfortunate blunder, well illustrating the contention that mere scientific coinages, however ancient, hardly ever sink into the understandings of the people so completely as native terms do.

When, however, a disease-name of scientific invention has once become welded into the language of the nation it almost invariably holds its own against subsequent attempts of scientists at emendation, just as a folk-name does. Take typhoid fever, for instance. Originally introduced by Louis in 1829 in his classical memoir on the subject,[31] *fièvre typhoïde* has been in general French use ever since, and was widely adopted in England about 1851. From an imaginary possible confusion between the adjective "typhoid," as applied to certain conditions of an asthenic, non-specific nature, and the specific fever itself, Dr. Murchison was led to invent an improved name, "pythogenic"—that is, filth—fever. This was, on the obvious ground of incorrect suggestion, at once objected to, was never very widely accepted, and is now quite obsolete. Dr. Wilks of Guy's Hospital, for the same theoretical reason, proposed "enterica" or "enteric fever" as a preferable term. This has had a more general acceptance unfortunately, especially among medical writers connected with Guy's Hospital, and is frequently to be found in medical reports and works. It has, however, never gained a footing in the literature or language of the people, and will, therefore, when it has produced its only effect, that of confusing the lay mind, finally die a natural death. Meanwhile, even those very purists who object to the term "typhoid" as likely to confuse, agree that "enteric fever" is probably caused by the bacillus typhosus of Eberth. The German "typhus" in connexion with this disease is, in fact, to be retained, while the French "typhoid" is to be sternly rejected.

Beyond such historical interest as this paper may arouse, its aim is to draw attention to the principles on which disease-names have been successfully formed in the past and to offer a few suggestions for their formation in the future:—1. Since medical literature in this country has become essentially English, disease-names which are most in sympathy with the genius and structure of our language or are actually drawn from our speech are most suitable for adoption by us. Since the writing of our literature in Latin has for ever ceased, the attempted classicising of names introduced from other sources ought to be abandoned. It has, for instance, been attempted to Latinise "dengue" into "denguis," an absurd endeavour. 2. A disease-name once generally adopted should never on any pretence be changed. Such alteration only confuses the records of historical medicine. In many of the diseases described by older authors we vainly seek for their real nature under an unfamiliar nomenclature. On the other hand, imaginary disease-names invented in modern days for historical epidemics are equally misleading. The "black death" which ravaged Europe during the years 1348–50 with such terrible results is not to be found in any contemporary literature under that name, which has been shown by Dr. Murray in the New English Dictionary to have had no more recondite a source than Mrs. Markham's "History of England," published no earlier than the beginning of the present century for the instruction of children. 3. It is vain to attempt to replace a folk name or one widely adopted by the people by a new one deliberately coined by scholars, and this for the following reasons: first, whatever names may be accepted by medical men must be translated by them into the vernacular of their patients, and by a resulting reaction the vernacular name comes to be the commoner one with themselves; and, secondly, there is no continuity or unchangeableness in the terms invented by *savants*, which are amended, improved upon, and displaced by the next writer on the subject, or, even more absurdly still, by the very inventors themselves in a subsequent publication. A striking instance of this occurs in that excellent work, "Fagge's Principles and Practice of Medicine." In the first edition, published in 1886, German measles is termed "rötheln," but in the second edition, issued only two years later, it is promoted to the dignity of "rubeola." Meanwhile, some writers call measles themselves "rubeola" and others "morbilli"—a pretty confusion, indeed, for the subsequent historian to unravel. These nosologists are, indeed, like one of Thackeray's characters, Lady Southdown, who having forced her followers to accept Podger's pills and Jowler's religion, had by the time their adherence was secured become herself a doubter and expected them instantly to abjure those heresies, medical and theological, and to accept other prophets equally extreme. 4. All language is the result of natural growth and cannot be artificially created. It is, therefore, more scientific to accept the products of natural development than to indulge in an artificial and therefore ephemeral system of cultivation. 5. All disease-names are only labels by means of which the maladies themselves can be identified, discriminated, and classified, and those names are the best which are simple, distinctive, and express no theories of causation. It is the folk names which most often meet these requirements, and therefore deserve the widest adoption by us in the future.

THE LOCAL GOVERNMENT BOARD TWENTY-FOURTH ANNUAL REPORT (1894-95).

FOOD.

THERE was an increase in the number of the analyses made under the Food and Drugs Act during the last official year amounting to nearly 2300 samples over the number made in the previous period, despite which the returns show that the proportion of adulterated samples was considerably below the average of the past three years—viz., 10·3 per cent., which *is the lowest percentage of adulteration since the passing of the Sale of Food and Drugs Act in 1875*. We take this as a positive proof that with the increase of vigilance on the part of the authorities to exercise their powers there has resulted a distinct decline in fraudulent practices which, during the operation of the Act, is without parallel. We have again and again insisted that a greater number of samples per head of population should be taken, and that in those districts where the Act was inoperative through the inaction of the authorities the Local Government should stir them up to their sense of duty in this matter. And the result has been satisfactory. There is still room, however, for improvement, since the present report shows that in all there were thirty-seven districts with an aggregate population of nearly two millions in which the Acts were entirely or almost entirely ignored. What is it that prevents no less than eleven county councils and the town councils of thirteen boroughs (including Great Yarmouth with a population of 49,334) and the thirteen boroughs including important places like Norwich, Stockport, Northampton, Ipswich, Warrington, and Tynemouth from making the slightest attempt to carry out the Acts which aim at providing a pure food supply for the people? We cannot believe that the food supply of these districts is so free from reproach that the application of the Act would be superfluous. We rather think that it is indifference on the part of the authorities, and steps should be taken to represent to these authorities the important gap they leave unstopped in carrying out their administrative duties. Looking down the list of the various articles of food that were collected for analysis we find that milk as in previous years was the chief subject of adulteration. Of the 16,305 samples of milk analysed no less than 1868, or 11½ per cent., were returned as adulterated. There is little doubt, however, that many samples passed as genuine were probably watered so as to be just within the limits of average quality. Such specimens of milk can only be dealt with by fixing a fair but not too low standard. Bread appears to have been tampered with only to the extent of rather less than 1 per cent. of the samples examined. The percentage of adulterated samples of butter fell last year to 10·4 whereas in the previous report it was 13·7. With the exception of 1888 this is the lowest record since the passing of the Act. Of 1724 samples of coffee examined 180, or 10·4 per cent., were condemned, a result which, compared with previous records, shows a distinct improvement; 29 samples of sugar were condemned out of the 397 samples

Digitized by Google

nalysed. This adulteration related chiefly to the use of olouring matter with beet sugar to imitate Demerara rystals. The practice of adulterating pepper to a very onsiderable extent appears to have very sensibly diminished, ince only 10 samples were condemned out of a total of 1609 nalysed; 50 samples of wine were passed except 1, which ras a British sherry proved to contain no alcohol, but com- osed of sugar, a little essence, and bisulphide of soda. The nly claim to sherry was its colour. About 7 per cent. of he samples of beer taken were condemned on account of xcess of salt, and there were cases also in which salicylic cid had been used as a preservative. Notwithstanding that n exceedingly low standard of strength for spirits was fixed y the Sale of Food and Drugs Act there is evidence of nuch adulteration of spirits; 17·7 of the samples were ondemned on this score. The penalties imposed amounted o £524 odd, representing 466 cases in which proceedings were instituted, 404 of which were successful. Of 1116 amples of drugs submitted for analysis, 125, or 11·2 per cent., were unsatisfactory. These were chiefly nitre, rhubarb, cream of tartar, and sulphur. Ten per cent. of the samples of ginger collected proved to be fraudulently mixed with spent ginger. Lastly, it is interesting to note that of the 39,516 samples analysed in 1894, all but 174 were obtained by officers of local authorities. The result showed adulteration to the extent of 10·3 per cent. The result of analysis of samples obtained by private purchase showed adulteration to the extent of 27·6 per cent. The Act is working very fairly well considering the difficulties that are connected with its administration, but we still urge that the results would be even better if there were less apathy on the part of many of our administrative bodies and if more samples were taken per head of the population. We should like to see, more- over, the barrier between Somerset House and the public analyst broken down, the question of standards settled, and an improved system of taking samples adopted. But these are points which we hope will be dealt with by the Select Committee on Food Products Adulteration, who have nearly finished their labours.

WATER.

Recent abnormal seasons, as, for example, a period of unusual drought followed by exceptional cold, have had a large share in bringing the question of metropolitan water- supply into peculiar prominence and have involved, of course, a more expanded treatment of the subject in the annual report of the Local Government Board. Increased storage is the question chiefly affected. Major-General Scott says that if reservoirs were constructed on a large scale for the purpose of impounding the river water during freshets the influence of the minimum or dry-weather flow of the Thames as a factor limiting the capacity of the river for the supply of the metropolis would be to a considerable extent eliminated.

The quantity of water daily abstracted for the use of the metropolis is but a small fraction of the average dis- charge and the withdrawal of the quantity taken by the companies can have no appreciable effect on the *régime* of the river in a general sense. This does not obtain, however, in the case of the Lea, although here also the impounding of water during freshets would avoid any serious reduction in the volume of discharge. On Aug. 8th, 1894, the East London Water Company were compelled to shut off the supply to three-fourths of the houses within their district between 8 P.M. and 6 A.M., which was continued until Oct. 28th, when in consequence of rain the water-supply rose rapidly and the constant supply was reverted to. Inadequate provision for storage was the cause of the failure to keep up the supply. The completion of the reservoirs provided for in the East London Company's Act of 1894 will about double the storage capacity available, but, as Major-General Scott observes, there is no finality in such works with a population increasing in that district at the rate of 20,000 persons per annum, so that the necessity for looking forward and beyond the scope of the authorised works will after a few years become apparent. In any case, all possible con- tingencies—drought and frost—must be provided against, and in adopting a basis for calculation the probable yield of water in normal weather is obviously no datum. All these are interesting observations connected with the projected new schemes for obtaining water further afield. The system of constant supply, we are glad to learn, has been considerably extended during the year and much waste has been prevented by a system of inspection and by the installation of waste indicators. To provide against emergency cisterns must still be employed, but a draw-tap on the supply-pipe should, as we have urged before, be used for drinking and cooking purposes. Interconnexion of the mains of several companies as a provision against the failure of one source of supply has been effected to some extent, but not so fully as is desirable.

Professor Frankland's report on the quality of the supply is full of interesting reading. He finds that the organic matter present in the river waters as delivered in London was to a very large extent of vegetable origin. On the whole, the degree of organic purity has been maintained. The report contains some interesting observations on the conditions most inimical to bacterial life in river water. The number of microbes in Thames water is determined mainly by the rate of flow of the river or, in other words, by the rainfall, and but slightly, if at all, by either the presence or absence of sunshine or of a high or low temperature. It is true that sunshine, as Marshall Ward has shown, is a powerful germicide, but it is probable, Professor Frankland thinks, that the germicidal effect is greatly diminished, if not entirely prevented, when the solar rays have to pass through a comparatively thin stratum of water before they reach the living organisms. He then proceeds to show the efficiency of the system of sand filtra- tion adopted by the water companies, in regard to the removal of organisms. The conditions of highest efficiency are next considered. It was impossible to refer to this subject without alluding to the admirable series of experi- ments undertaken by Mr. G. W. Fuller at the instigation of the State Board of Health of Massachusetts. The results of this investigation, coupled with those of Professor Frankland, are doing great service in demonstrating what really are the laws of water filtration. They afford, as Professor Frank- land observes in his concluding remarks, fairly conclusive data for the guidance of engineers of the London water companies in all ordinary seasons; but the severe weather which prevailed in England a year or so ago has brought to light some entirely novel phenomena affecting the filtration of water which will require to be carefully studied and which are at the present moment engaging his earnest attention. The results will be awaited with deep interest.

THE NILE CAMPAIGN.

ALL arrangements connected with the advance of the Anglo-Egyptian force seem to be progressing favourably, and the news that the force was advancing southward is stated to be already productive of good effects in giving confidence, on the one hand, to those tribes who are friendly and looking forward to being emancipated from the tyrannical rule of the Dervishes, and, on the other, in probably drawing off Osman Digna's force from the beleaguered garrison of Kassala in the directions of Suakim and Dongola. A Dervish force has reached Kokreb, a station fifty miles to the west of Suakim. The telegraph wire between Korosko and Murat Wells has been again cut, and the Dervishes are reported to be in considerable numbers on the Assouan-Berber road threatening the Murat post and probably intending, also, to make an attack on the Egyptian fort Heliab on the Red Sea about 200 miles north of Suakim. The garrison at Suakim has been strengthened, but it appears highly probable that the force at that station must be still further increased, and this could be easily and promptly done by sending there some vessels from the British fleet and a native force from India, which might not only aid in the defence of Suakim, but take part in the expedition in other directions if necessary. Some portions of our Indian army are admirably adapted for a campaign in Egypt; they are well suited for the climate and the work, and thoroughly disciplined and reliable. No doubt a very marked change has been effected in the Egyptian army under the discipline and leadership of English officers, and it may be confidently expected that the Egyptians will give a very different account of themselves under present conditions from what has hitherto sometimes been the case in their fights with the Arabs. Still, it has to be borne in mind that Osman Digna's troops are a very brave and formidable

Digitized by Google

enemy, attacking their foes with a daring and fanatical impetuosity which the Egyptians might not be able to resist. The Soudanese portion of the Egyptian force, however, have always proved themselves in point of courage excellent and reliable troops in the field. But a contingent of specially selected troops from the native army of India is specially adapted, as we have said, to the country and this kind of warfare, and with a comparatively small number of English battalions added to the Egyptian force there would be no reasonable doubt whatever of the success of the expedition. It seems possible that an officer of high rank and proved capacity on Egyptian fields may yet be sent out from this country in supreme command of the expedition, and we quite concur with the writer of "Egypt and its Frontier" in the *Fortnightly Review* for this month in his very high estimate of Sir Redvers Buller's special and proved qualifications for such a post. Meanwhile, railway extension works are being actively carried out and very large quantities of railway plant and supplies have been pushed forward. Some engineering experts have also arrived at Wady Halfa *en route* for Sarras in order to examine and report on the work that has been done in this respect. The heaviest task has, of course, during the present stage of the expedition, fallen upon the transport department. The heat has of late been great—unusually great for the season, it is stated—and dust storms have occurred; but the force is in good health and spirits, and generally satisfactory progress has been, and is being, made in all that concerns the expedition. The greatest activity has prevailed at the Royal Arsenal, Woolwich, in fitting out and sending off stores for Egypt and the campaign. From all we can learn as to the efforts that have been made in Egypt and this country the medical and hospital services of the expedition should be well supplied with men and material. The expedition is no doubt an undertaking of difficulty, and altogether, apart from fighting, it may cost much in the way of loss of health and money. But the province of Dongola is a fertile, rich, and paying part of the Nile country, and the rule of the Dervishes is a tyrannical one. It is, after all, by opening out the communications—by means of railways and other facilities for commercial intercourse—between the Nile provinces and Egypt and Cairo that real progress will be made and peace established on a satisfactory basis.

LITERARY INTELLIGENCE.—An English translation of Dr. P. G. Unna's exhaustive treatise on the Histopathology of Diseases of the Skin, at the hands of Dr. Norman Walker of Edinburgh, is about to appear. The German edition, a volume of some 1200 pages, deals in a more exhaustive manner than has hitherto been attempted with the histological changes found in almost every known disease of the skin, and forms a monument to the accuracy, energy, and painstaking industry of the author. It marks a fresh step in the scientific study of skin diseases from an anatomical standpoint. But Dr. Unna's German, though of course good, is not of a kind which is easy to be read by those who are not perfectly familiar with the language. An English rendering of the work will therefore be welcome among English-speaking people. Numerous additional illustrations will be included, drawn from Dr. Unna's collection of specimens.

THE DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—An ordinary meeting of this society was held on March 25th, Dr. P. H. Pye-Smith, F.R.S., President, being in the chair. The following cases, &c., were exhibited:—The President: Photographs of Unusual Warts of the Face limited to the Tract of the Fifth Nerve and complicated by a Nævus which appeared before the Warts, the patient also having similar warts on the mucous membrane of the palate. Dr. T. D. Savill: (1) Morphœa Nigra in a girl aged thirteen years; and (2) (for Mr. Tay) Lupus Verrucosus. Dr. A. Eddowes: Lupus Erythematosus. Dr. P. S. Abraham: (1) Multiple Lupus (for Mr. Bidwell); (2) Prurigo of Hebra; (3) Vesicating Erythema; and (4) Pemphigus in a woman aged eighty years; also three cases for diagnosis. Dr. Eddowes read a paper on Warts on the Feet. Dr. Stowers exhibited microscopic sections of the Skin Eruption of Variola. The President, Dr. Bowles, Dr. Savill, Mr. Hare, Dr. Abraham, Dr. Eddowes, and Dr. Stowers took part in the discussions which followed. It was announced that the next meeting would take place on April 22nd.

THOMAS WAKLEY,

THE FOUNDER OF "THE LANCET."

A BIOGRAPHY.[1]

CHAPTER XV.

The Terrible Accusation of Malpraxis against Mr. Bransby Cooper.—The Style and Matter of the Libel.—Wakley Defends himself Personally.—A Legal Point decided in his Favour.—The Evidence for the Defence.

IN the preceding chapter it was indicated that the summary of the Hospital Reports as given by Wakley and his staff in THE LANCET would be limited to a consideration of the reports printed up to the year 1828. The reason of that limitation is as follows. On March 29th, 1828, there appeared in these columns the report of a case of hospital malpraxis, which led to the most sensational lawsuit that Wakley was ever engaged in, not excepting his suit against the Hope Fire Assurance Company. This was the case of Bransby Cooper *v.* Wakley. The report out of which the case arose was the most outspoken denunciation of a piece of hospital malpraxis possible to conceive. It was written in so sensational and even malignant a style that the harmfulness, nay, the terrible mischief, of sensational journalism was as remarkably illustrated by it as was the power for good of a strong vindication of the rights and usefulness of publicity. It was at once the very best and the very worst that such a report could be. To the public it did the greatest good. To the medical profession it did both good and evil. It inflicted a serious blow upon the prestige of the hospital surgeons. But the widespread repudiation by the rank and file of the profession of the systems that could sanction such treatment as was alleged to have been meted out to Mr. Bransby Cooper's patient did public honour to the feelings of medical men. On the whole the good may be said to have outweighed the evil. To the individuals concerned no half measures were possible. The plaintiff, Mr. Bransby Cooper, was inferentially called a murderer, and the defendant to justify his attitude followed the report by a leading article saying that he cared nothing for the result, but maintained the accuracy of his words, and not only his right but his duty to publish them.

The operation in question took place at Guy's Hospital, and was a lithotomy performed by Mr. Bransby Cooper, then a surgeon to the institution of three years' standing. The patient was a strong, middle-aged countryman, for whom the procedure of cutting for stone should not under ordinary circumstances have had any particularly grave risk. A definite rate of mortality occurred in such cases, and that should have been the measure of the risk. The operation, however, took an enormous time and resulted fatally. Was this time consumed in honest attempt to combat extraordinary difficulties—in which case the unlucky surgeon would have commanded the sympathies of the medical profession and the public alike? Or was it frittered away in unsurgical bungling? The article in THE LANCET left no doubt in the reader's mind what was the conclusion of the writer.

The report was headed:—

THE OPERATION OF LITHOTOMY BY MR. BRANSBY COOPER WHICH LASTED NEARLY ONE HOUR!

A footnote to the title was as follows: "The following passage occurs in John Bell's great work on surgery: 'Lon

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII.-XIII., and XIV. were published in THE LANCET, Jan. 4th, 11th, 18th, and 25th, Feb. 1st, 8th, 15th, 22nd, and 29th, March 7th, 14th, 21st, and 28th, and April 4th respectively.

Digitized by Google

and murderous operations, where the surgeon labours for an hour in extracting the stone, to the inevitable destruction of the patient' "; while the opening passages of the report show well the spirit in which it was conceived and written.

"We should," it ran, "be guilty of injustice towards the singularly gifted operator, as well as to our numerous readers, if we were to omit a full, true, and particular account of this case. It will doubtless be useful to the county 'draff' to learn how things are managed by one of the privileged order—a hospital surgeon—nephew and surgeon, and surgeon because he is 'nephew.' The performance of this tragedy was nearly as follows:—"

The account which followed was short but horrible, and its horror was accentuated by the dramatic brevity of the recital. The word dramatic is used advisedly, for the report was cast in dramatic form. It was divided into Act 1 and Act 2, while the result of an examination of the body after the death of the patient was added as an epilogue. The first Act set out the preliminary steps of the operation, which took twenty minutes, and clearly insinuated that the original incision having been wrongly made the operator lost his proper appreciation of the anatomical geography of the region and attempted violently to effect a passage with his forceps where no incision had cleared the way—that, in fact, in his attempts to reach the bladder he made a false passage. The second Act, stated to have lasted half an hour, accused the operator of having hopelessly lost his head. It described him as calling for all forms of instruments, notably for one, a scoop, that must have been useless until the foreign body was actually located; as asking for the assistance of his colleagues and even his dresser; as complaining in front of the patient, of course unnarcotised, of his utter inability to understand the cause of his own terrible failure to extract the stone; and, finally, when at last the operation was over, of attempting to explain the difficulties to the appalled assembly of surgeons and students while the conscious and dying patient still lay bound upon the operating table. No more terrible picture of incompetency, of want of skill, want of nerve, and want of heart could be imagined than the picture that was drawn. The epilogue to this terrible tragedy was in keeping. A brief description of the parts concerned in the operation was followed by the most unmistakable insinuation that the reason why Mr. Bransby Cooper had failed to extract the stone from the patient's bladder was because his forceps had not at first been in the bladder at all.

Although this report was brief it contained a terrible indictment of Mr. Bransby Cooper and also of Guy's Hospital, at that time possessing the first reputation in the kingdom for surgical practice. Stripped of all verbiage and raising every insinuation to the dignity of a statement—which no one could have read the article without doing—the gist of THE LANCET report was as follows: That the authorities of Guy's Hospital had elected Mr. Bransby Cooper upon their staff because he was Sir Astley Cooper's nephew; that he was an unskilful surgeon, and had consequently killed a patient by his gross mistakes during the performance of an operation; that he was so concerned at the public exhibition of ignorance which he felt himself to be making that he behaved with brutal callousness to the unfortunate sufferer. (It must not be forgotten that we are writing of the days when anæsthetics were unknown and when, therefore, a premium was set upon rapidity of operation; while anything like a consultation in front of a conscious patient was held to be grossly unprofessional and a grave confession of weakness.) Nepotism on the part of the management, malpraxis on the part of the officer—these had been Wakley's outspoken and repeated accusations against those responsible for the management of the London hospitals. Time after time he had said that these two factors were working secretly for ill, and equally often he had promised that any mischief so produced should be dragged into the light of day. This was a unique occasion for keeping his word. *One* set of circumstances proved him right in *both* of his recurrent accusations. He printed those circumstances in a shape which could have left no doubt that he believed in the righteousness of his action, and he referred to them subsequently in articles even severer than the original report, and designed to open the eyes of the country "draff," as the metropolitan magnates of those days contemptuously designated their provincial brethren.

Mr. Bransby Cooper had no alternative but to bring an action against Wakley. If he had desired to do otherwise it is certain that those responsible for the medical and administrative management of the charity would not have permitted him, but he never had any doubt as to his course. He felt that his back was against the wall and that if he could not beat off the foe he was a ruined man, for the article in THE LANCET had been widely copied into the lay press, and a storm of popular comment was blowing round the names of Wakley, Bransby Cooper, Sir Astley Cooper, THE LANCET, and Guy's Hospital. The case originally stood to be heard in the Court of King's Bench on Oct. 29th, 1828, but was postponed at Mr. Brougham's request, made on Wakley's behalf, until Dec. 12th, when Wakley announced his intention of defending himself in person.

At half-past nine o'clock on the morning of Friday, Dec. 12th, 1828, the case of Cooper *v.* Wakley came on for hearing in the Court of Queen's Bench before Lord Tenterden and a special jury. The case excited the most intense interest in the public mind. "Long before the sitting of the court at half-past nine o'clock," says the *Times* of Dec. 18th, 1828, "the different avenues leading to the court were so crowded that there was scarcely any possibility of forcing a passage. It was with the utmost difficulty, with the most active assistance of the constables and officers of the court that the counsel, jury, and witnesses could obtain an entrance." On the second day the approaches were still more thronged. At an exceedingly early hour persons were standing without the door anxious to obtain admission into the court. The officers, however, adopting a different course from that of Friday, kept the crowd at the outer door until the counsel, jury, and witnesses were admitted; those who had assembled merely out of curiosity were not allowed to force their entrance. Several contemporary journals, THE LANCET itself, *The Times*, *The Sun*, and *The Weekly Dispatch*, narrate a curious little incident that happened in the crowd without Westminster Hall. A gentleman who was carrying a sword-stick had the case of it crushed by the excessive pressure of the crowd. The point of the sword came out through the bulging rent in the sheath, and was forced into a by-stander's thigh. The tension of waiting and the general imagination of the fevered crowd, which was certainly set upon the consideration of horrors, gave to this small accident a serious importance, and all sorts of stories of attempts at assassination were buzzed about, the excitement not subsiding until at last the court was opened to the public.

The defendant appeared in person punctually, being assisted by Mr. Brougham and Mr. FitzRoy Kelly, while Sir James Scarlett, afterwards Lord Abinger, Mr. F. Pollock, afterwards Chief Baron Pollock, and Mr. Scarlett represented the plaintiff. Wakley brought with him into court the cast of a child representing the position in which a patient is tied when undergoing the operation of lithotomy, the bones of a full-sized pelvis, and specimens of all the instruments alleged in the libellous report to have been used by Mr. Bransby Cooper in the fatal operation. These were placed upon a table in the well of the court.

Mr. Scarlett opened the pleadings by reading the libel, which consisted of the report of the case and the leading article upon it that had appeared in the next issue of THE LANCET. The leading article added nothing to the facts in the report, but was a most damning commentary upon

Digitized by Google

the circumstances, setting out the details and calling attention to them with interjections, *nota benes*, and all sorts of verbal pilcrows. The writer, who was Wakley himself, did certainly make a disclaimer of being actuated by any malicious feeling towards Mr. Bransby Cooper, whom he was willing to believe a kind-hearted man justly popular among his pupils; but this concession was followed by a bitter summing up of the case against him. It could not be denied, wrote Wakley, that Mr. Bransby Cooper had taken nearly an hour to perform an operation whose average duration in the hands of skilful surgeons was six minutes. And it could not be questioned that he was indebted for his appointment to the staff of Guy's Hospital to his relationship to Sir Astley Cooper and not to his own skill.

Immediately upon the libel being read an extraordinary discussion followed. Sir James Scarlett rose to open the case, when Wakley insisted that as he had charged the plaintiff with unskilfulness and intended to prove the truth of his pleas he ought to proceed with his case before the plaintiff's case was gone into. Wakley's argument was ingenious and successful. While admitting that in general a plaintiff has the right to open his case and by consequence to have the general reply,

> For courts of justice understand
> The plaintiff to be eldest hand,

he submitted that there were exceptions to this rule and that his attitude of pleading justification only and not innocence placed his case in their category. The cases he relied on as precedents were three. The first was one of trespass, where the defendant admitted his entrance on to the plaintiff's property but pleaded right of way. Here the affirmation of the issue being thrown upon the defendant, Mr. Justice Bayley, a great jurist, and later a Baron of the Exchequer, held that the defendant had the right to begin. The other two were cases of assault and battery, where the defendant pleaded justification without adding "Not Guilty." In each of these cases Chief Justice Best and Mr. Justice Bayley on consultation with brother judges had severally allowed the plea. It was Brougham who supplied Wakley with the legal information necessary to make his representation to Lord Tenterden, but it can be imagined that to hear so technical a point raised by a layman created no little sensation in the court, where the general feeling was rather one of sympathy for Wakley in his foolhardy attempt to conduct his own case against one of the most powerful advocates at the Bar. Sir James Scarlett strenuously opposed Wakley's application. Lord Tenterden, after a few minutes' consultation with two of his learned brothers in the adjoining courts, decided in Wakley's favour, who immediately rose to address the jury, having secured by his successful application the right to a general reply, which, with such an opponent as the Attorney-General to deal with, meant an enormous stride towards victory. Although Wakley obtained his point by relying upon precedents he himself established a precedent while so doing, for the principle that had been allowed to prevail in cases of trespass and assault has never before been quoted as holding good in a case of libel.

Wakley's opening speech was a vindication of the view that it was of the utmost importance to the public that the management of our hospitals should be efficient and that only men possessed of the highest professional skill should be elected honorary medical officers to these noble charities. Solely to maintain a high standard in the management of hospitals and in the skill and knowledge of those empowered to treat the sick and teach the students within their walls, he had published the addresses of hospital lecturers and the reports of clinical and operative procedure at the different theatres. In the ordinary course, and with no special malice whatever, he had received a report of an operation which had taken place at Guy's Hospital on a certain day. The report told so extraordinary a story that he had abstained from printing it until he had personally been assured by the contributor that it was true word for word. He then considered that he had no other course to pursue in his public character than to print the report and take the consequences. He then called his first and, as it turned out, most valuable witness, a Mr. Partridge of Colchester.

Mr. Partridge was a voluntary witness, unknown personally to Wakley, and only asked to give evidence the very day of the trial. In Brougham's brief, a document made interesting by the fact that it has upon it the pencil notes of the eminent lawyer and his exceedingly bad sketches of the anatomical distribution of the parts concerned in the operation of lithotomy, Mr. Partridge's name does not occur, while the names of all the other witnesses are given. Mr. Partridge said that he had practised for fourteen years and was a prominent citizen in Colchester and an alderman of the borough. He had witnessed numerous lithotomies and had performed the operation eighteen times himself. He considered the report of the operation in THE LANCET correct; and he had been sitting immediately behind Mr. Bransby Cooper all the time. The operation lasted nearly an hour. Mr. Cooper appeared perplexed and hurried; he varied his instruments perpetually and irrationally; he expressed his wonder at the delay of extraction in front of the conscious and writhing patient. If the operator had known what he was about, said Mr. Partridge, he would have extracted the stone immediately.

Cross-examination, though severe, quite failed to shake this witness. His professional position was unimpeachable, and his motive for giving evidence could only be a desire to assist what he believed to be the cause of justice, for he was not a member of the staff of THE LANCET and did not know Wakley by sight and scarcely by name until the morning of the trial. Wakley's other witnesses did not turn out so well. They testified to what they saw, and this in each case amounted to a confirmation of the report, which formed the substance of the libel to be justified, but their answer under cross-examination to credit were not satisfactory. The first of these gentlemen, though a Licentiate of the Society of Apothecaries, was found to have put in false certificates to his age that he might obtain the diploma earlier than the regulations allowed. The second gentleman had succeeded Wakley as assistant to his (Wakley's) brother-in-law, Mr. Phelps of Beaminster, and was obviously interested in the issue of the case for reasons other than a desire to see abstract justice done. The third gentleman was found to be intimately acquainted with Mr. Lambert, who wrote the report. It was felt by everybody that had it not been for Mr. Partridge Wakley's selection of eye-witnesses out of a crowd of over two hundred persons would have been very unfortunate.

Mr. Lambert, the author of the report, came next. He maintained that the report was true and rather an understatement than an over-statement of facts. He had attended the post-mortem examination and there observed appearances which he considered bore out the accuracy of his report, inasmuch as they went to show that Mr. Cooper's first attempts at extraction were wrongly directed—that, in fact, he had hopelessly mistaken the anatomy of the region. Mr. Lambert did not come out well on cross-examination. He was made to confess that he had had a personal quarrel with Mr. Bransby Cooper, and that the tone of previous reports from his pen had caused his exclusion from the wards of Middlesex and St. Thomas's Hospitals. He was also revealed as the cousin of the previous witness, who had obtained the Licentiateship of the Society of Apothecaries by making a false statement on oath. As a whole he maintained the accuracy of his report. Sir James Scarlett was not able to shake him in his account of what happened, but

Digitized by Google

he was able to prejudice his evidence in the eyes of the judge, and he did so.

Mr. Lambert was followed, fortunately for Wakley's case, by two rather better witnesses, in that their purity of motive was indubitable. Both testified to the length of time occupied by the operation and to the pitiable condition of hurry and perplexity to which Mr. Bransby Cooper was reduced by his ill-success at first. Wakley's last witness was the treasurer of St. Thomas's Hospital, a Mr. Benjamin Harrison. He was a very unwilling witness who appeared on subpœna, and in cross-examination gave Mr. Bransby Cooper an excellent character as a surgeon. While, however, he swore that relationship to Sir Astley Cooper had had nothing to do with Mr. Bransby Cooper's election to the staff of Guy's Hospital, he would not swear that the gentleman who had been passed over, who was no relation to Sir Astley Cooper, but senior to Mr. Bransby Cooper, was not a better surgeon than the plaintiff, who had been preferred to him. Mr. Wakley then closed his case, and the court adjourned until the following day, Sir James Scarlett submitting that he would rather address a fresh jury than a jaded one.

(To be continued.)

THE McEWAN HALL OF THE EDINBURGH UNIVERSITY.

THIS magnificent piece of architecture, which has been in process of erection for several years, is now within a few months of its completion. The hall is part of the original plan supplied by Dr. Rowand Anderson for the new University buildings which have been constructed in Teviot-row and Park-place. For the carrying out of this part of the plan the city and University are indebted to the princely generosity of Mr. W. McEwan, M.P., who in 1888 undertook to defray the entire cost of building this great hall for the use of the University. The Senatus, in a minute passed in 1888, duly expressed their appreciation of the magnitude and splendour of the gift and on the same occasion resolved that for all future time the hall shall bear the name of its donor. The hall, it is expected, will cost not less than £60,000 or £70,000, and will be seated for 3000 persons. On its northern frontage it joins the medical buildings in Teviot-place. Its east elevation, which is semicircular in form, is now seen to great advantage by the demolition of the houses in Bristo-street. The hall stands on the site of what was formerly Park-street. The architect, keeping in view the purposes for which the hall would be used—public ceremonials connected with the University, and the conferring of degrees—has based his design on the form of the ancient Greek theatre, which, it is believed, is the best adapted for allowing the largest number of spectators to see and hear well. The shape of the hall is semicircular, with the flat side of the semicircle to the west, where are placed the organ loft and platform which is provided at the back with a series of oak stalls for professors. The hall has two walls, an outer and an inner, which allow for a corridor between them on the ground floor 12 ft. in width. There are two galleries in the upper stages, the inner wall being opened up to the interior of the hall by a beautiful arcading of thirteen bays, each 15 ft. wide and measuring 48 ft. from the floor to the top of the arch. There is a beautifully carved stone frieze and cornice at the wall-head, with above it a coved clerestory with circular windows 7 ft. in diameter. The dome, which has in the centre a circular light 22 ft. in diameter, is constructed of steel and panelled with wood.

The height from floor to wall-head is 58 ft., and from floor to centre of dome 90 ft. The internal diameters of the outer and inner wall circles respectively are 134 ft. and 106 ft. From the outer circle to the back of the platform the distance is 107 ft. The platform opening is 52 ft. wide and is covered by an elliptical ceiling. The hall is to be lighted by electric light and the organ will be worked by electricity. The galleries are reached by two circular staircases in the outer circumference, each double, containing a separate stair for each gallery. From the inner circle are five doors giving access to the hall. The balustrades of the galleries, the pews in the galleries, and the panelling of the inner wall up to the level of the first gallery are in dark stained oak. The area floor is of oak, and on it the seats will be movable, with the exception of four tiers of fixed fauteuils ranged round the back of the semicircle. The principle staircase occupies the south angle of the building, and the north angle is formed by the base of the proposed campanile tower which forms part of the original design, but still remains unexecuted. Another donor is wanted to complete this part of the scheme. The tower in the plan is 270 ft. in height. For purposes of ventilation there will be a fan placed in the basement of the building. The masses of masonry on the external elevations have been disposed with telling effect. The wall is divided vertically by buttresses corresponding to the internal divisions of the hall, and standing well out from the face of the wall. Between two of the buttresses on the north-east side there is carved the following inscription.—

Hanc Aulam Academicam
Gulielmus McEwan
Universitati Edinburgensi
Libero Animo Donavit
MDCCCXCIV.

The external elevations show horizontally three divisions. In the lower, which is panelled, are the windows for lighting the corridor; the upper section is arcaded in red stone and the wall is finished by a cornice and open balustrade. The clerestory and the dome rise above these, the dome being covered with lead and surmounted by an ornamental lantern 30 feet high. The height from street level to the top of the lantern is 130 feet. In the outer circle are seven doorways for entrance and exit, the principal one being in the east elevation. There is a staircase giving access to the hall from the quadrangle of the University which is very pleasing in effect. The constructive part of the work in connexion with the erection of this hall has been finished for some time, but the opening has been retarded by the execution of an elaborate scheme of decoration. The scaffolding has now, however, been cleared away and the principal decorations are completed.

The decorative part of the work was placed by the trustees in the hands of Mr. W. M. Palin, who has now been engaged for over two years in this part of the undertaking. Mr. Palin has followed the relief as opposed to the flat method of painting in the mural decoration. His figures are executed in strong relief and his backgrounds have been given perspective depth. The dome, which is most elaborately treated, shows running round its inner edge a broad blue band, on which is inscribed in golden letters the words, taken from Scripture: "Wisdom is the principal thing; therefore get wisdom: and with all thy getting get understanding. Exalt her and she shall bring thee to honour." In the decoration of the dome the artist has endeavoured to produce on a large scale the effect of an enamelled jewel, which he has done by painting on a background of gold and using in the drapery of his figures the colours of precious stones. The dome is divided by the ribs into fifteen compartments, these being subdivided into smaller panels, the upper of which are filled with ornament in white and gold, while the lowest and largest panel in each compartment shows a seated female figure in double life size. There are thus fifteen figures in the half circle of the dome, of which thirteen are named. Reading from the left they are: "Astronomy," "Mathematics," "Poetry," "History," "Divinity," "Philosophy," "Medicine," "Oratory," "Jurisprudence," "Fine Arts," "Music," "Biology," "Physics." Over the top of the platform opening on the west wall is a large panel measuring 100 ft. across and narrowing as it ascends to the apex. On it is painted a representation of the "Temple of Fame." The composition contains eighty or ninety figures, on a scale of 9 ft., representing groups of philosophers and students conversing together or ascending steps to a raised piazza, where there is a temple in the background. At the apex of the panel three goddesses are painted representing "Science," "Art," and "Literature." The figures are in strong relief with draperies of blue, red and violet, and red and green respectively. In front of the figures are Cupids with tablets. On each side of the platform opening on the west wall is a large panel, 24 ft. by 13 ft., with a lunette above it. On the right "Minerva" is represented, draped in green and red, as the tutelary

Digitized by Google

deity of the University, seated on a marble throne in the grove of Academia receiving the gift of the building. Into one of the figures, arrayed in classic robes, standing at the sides of the steps of the throne the artist has introduced a portrait of Mr. McEwan, which is an excellent likness of the generous donor. The panel balancing this on the other side gives a representation of "Fame" as a female figure in pale green and gold seated on a throne with a trumpet in one hand and a laurel wreath in the other. An aspirant in red robes kneels in front of her while groups of men are ranged on either side. The angle panels of the arch are decorated like those alongside of them. On the right are two figures representing "Perseverance" and "Intelligence," while on the left are "Imagination" and "Experience." On the walls of the clerestory, which are painted sky blue and gold, are inscribed the names of eminent men who have been connected with the University. The carved stone frieze is very effectively picked out in gold. The ceiling of the first gallery is panelled in blue and gold, while the roof of the second is treated in a warm sepia tint. The paintings and dome decorations were finished in oil on canvas in the artist's studio and afterwards affixed to the walls and dome. The colouring has been necessarily strongly executed to allow for the mellowing influence of age.

There can be no doubt that on the completion of the McEwan Hall the University of Edinburgh will possess an academic building unequalled in any other university in the United Kingdom.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6544 births and 3814 deaths were registered during the week ending April 4th. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 20·7 to 18·8 per 1000, further fell last week to 18·3. In London the rate was 17·9 per 1000, while it averaged 18·6 in the thirty-two provincial towns. The lowest rates in these towns were 11·7 in Portsmouth, 12·2 in West Ham, 13·0 in Huddersfield, and 13·1 in Cardiff; the highest rates were 21·5 in Preston, 22·0 in Liverpool, 22·1 in Manchester, 24·3 in Salford, and 26·7 in Birkenhead. The 3814 deaths included 615 which were referred to the principal zymotic diseases, against 578 and 631 in the two preceding weeks; of these, 247 resulted from measles, 183 from whooping-cough, 68 from diphtheria, 48 from scarlet fever, 39 from diarrhœa, 30 from "fever" (principally enteric), and not one from small-pox. No fatal case of any of these diseases occurred last week in Halifax; in the other towns they caused the lowest death-rates in Portsmouth, Swansea, Preston, and Hull, and the highest rates in London, Manchester, Plymouth, Sunderland, and Birkenhead. The greatest mortality from measles occurred in Plymouth, Birkenhead, Manchester, Burnley, and Sunderland; from scarlet fever in Bolton; from whooping-cough in Birmingham, Leeds, Sheffield, London, and Plymouth, and from "fever" in Norwich and in Blackburn. The 68 deaths from diphtheria included 45 in London, 5 in Birmingham, 4 in West Ham, and 3 in Liverpool. No fatal case of small-pox was registered either in London or in any other of the thirty-three large towns. There were 23 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 4th inst., against 42, 43, and 33 at the end of the three preceding weeks; 2 new cases were admitted during the week, against 4, 9, and 2 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2676, against 2764, 2773, and 2744 on the three preceding Saturdays; 186 new cases were admitted during the week, against 217, 277, and 224 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 433 to 285, in the four preceding weeks, further fell to 270 last week, and were 131 below the corrected average. The causes of 56, or 1·5 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Salford, Oldham, Sunderland, Newcastle-upon-Tyne, and in ten other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·6 and 18·9 per 1000 in the two preceding weeks, further declined to 18·7 during the week ending April 4th, but slightly exceeded the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 10·5 in Leith and 13·4 in Edinburgh to 21·6 in Dundee and 22·2 in Aberdeen. The 545 deaths in these towns included 21 which were referred to whooping-cough, 17 to diarrhœa, 8 to measles, 6 to "fever," 5 to scarlet fever, and 4 to diphtheria. In all, 61 deaths resulted from these principal zymotic diseases, against 70 and 52 in the two preceding weeks. These 61 deaths were equal to an annual rate of 2·1 per 1000, which was 0·8 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had declined from 35 to 21 in the three preceding weeks, were again 21 last week, of which 13 occurred in Glasgow and Aberdeen. The deaths from measles, which been 13 and 6 in the two preceding weeks, rose again to 8 last week, and included 4 in Glasgow and 3 in Greenock. The deaths referred to different forms of "fever," which had been 6 and 4 in the two preceding weeks, increased to 6 last week, of which 5 occurred in Glasgow. The 5 fatal cases of scarlet fever showed a slight further decline from the numbers recorded in recent weeks, and included 2 in Glasgow and 2 in Edinburgh. Of the 4 fatal cases of diphtheria 2 were returned in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 115 and 107 in the two preceding weeks, further declined to 87 last week, and were less than half the number in the corresponding period of last year. The causes of 37, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 28·3 to 24·8 per 1000, rose again to 25·5 during the week ending April 4th. During the thirteen weeks of last quarter the death-rate in the city averaged 25·3 per 1000, the rate during the same period being 19·5 in London and 17·7 in Edinburgh. The 171 deaths registered in Dublin during the week under notice showed an increase of 5 upon the number in the preceding week, and included 8 which were referred to the principal zymotic diseases, against 7 in each of the two preceding weeks; of these, 2 resulted from measles, 2 from diarrhœa, 1 from small-pox, 1 from diphtheria, 1 from whooping-cough, 1 from "fever," but not one from measles. These 8 deaths were equal to an annual rate of 1·2 per 1000, the zymotic death-rate during the same period being 3·7 in London and 1·3 in Edinburgh. The fatal cases of scarlet fever, which had been 4, 1, and 2 in the three preceding weeks, were again 2 last week. The 2 deaths referred to diarrhœa were within one of the number in the preceding week, while the mortality from diphtheria and whooping-cough corresponded with that recorded in the previous week. The fatal case of small-pox was the first registered within the city since January last. The 171 deaths in Dublin last week included 26 of infants under one year of age, and 48 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons exceeded those recorded in recent weeks. Two inquest cases and 3 deaths from violence were registered; and 64, or more than a third, of the deaths occurred in public institutions. The causes of 9, or more than 5 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING MARCH, 1896.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during March in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 8·4 per 1000 of the population, estimated at 4,435,955 persons in the middle of this year. In the three preceding months

the rates had been 11·5, 10·3, and 8·8 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in St. George Hanover-square, St. James Westminster, St. Giles, St. Martin-in-the-Fields, City of London, Bermondsey, and Lee; while they showed the largest excess in Clerkenwell, Mile End Old Town, Limehouse, St. Saviour Southwark, St. Olave Southwark, Camberwell, and Greenwich. The prevalence of small-pox in London during March corresponded with that in the preceding month, the 22 cases notified including 7 in Islington, 3 in Hackney, 3 in Lambeth, and 2 in Poplar sanitary areas. The Metropolitan Asylum Hospitals contained 33 small-pox patients at the end of March, against 75, 68, and 45 at the end of the three preceding months; the weekly admissions averaged 7, against 13 and 6 in the two preceding months. The prevalence of scarlet fever in London showed a further decline during March; this disease was proportionally most prevalent in Hampstead, Strand, Clerkenwell, St. George-in-the-East, Mile-end Old Town, St. Saviour Southwark, St. Olave Southwark, and Greenwich sanitary areas. The Metropolitan Asylum Hospitals contained 2688 scarlet fever patients at the end of March, against 2708, 2814, and 2867 at the end of the three preceding months; the weekly admissions averaged 234, against 250, 282, and 258 in the three preceding months. The prevalence of diphtheria in London during March showed a very slight increase upon that recorded in February; among the various sanitary areas this disease showed the highest proportional prevalence in Fulham, Hampstead, Whitechapel, Limehouse, Mile End Old Town, Camberwell, and Greenwich. There were 704 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of March, against 687, 682, and 715 at the end of the three preceding months; the weekly admissions averaged 99, against 99, 103, and 99 in the three preceding months. The prevalence of enteric fever in London showed a further marked decline from that recorded in recent months; this disease was proportionally most prevalent in Chelsea, St. Luke, and Mile End Old Town sanitary areas. Erysipelas was proportionally most prevalent in Clerkenwell, St. Luke, Shoreditch, and Limehouse sanitary areas. The 29 cases of puerperal fever notified during March included 4 in Greenwich, 3 in Islington, and 3 in Newington sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas, the deaths occurring in the institutions of London having been distributed among the different sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, March 28th, the deaths of 6601 persons belonging to London were registered, equal to an annual rate of 19·4 per 1000, against 17·3, 18·4, and 20·0 in the three preceding months. The lowest death-rates during March in the various sanitary areas were 10·1 in Hampstead, 11·5 in Stoke Newington, 11·7 in Lewisham (excluding Penge), 12·9 in Lee, 13·9 in St. Olave Southwark, 14·2 in Woolwich, and 15·3 in St. George Hanover-square and in Battersea; the highest rates were 23·8 in Bermondsey, 24·1 in Holborn, 24·6 in St. George-in-the-East, 25·5 in St. George Southwark, 25·9 in Marylebone, 27·8 in St. Luke, and 28·8 in Bethnal Green. During the four weeks of March 1262 deaths were referred to the principal zymotic diseases in London; of these, 552 resulted from measles, 886 from whooping-cough, 193 from diphtheria, 69 from scarlet fever, 32 from diarrhœa, 27 from enteric fever, 1 from an ill-defined form of continued fever, and 2 from small-pox. These 1262 deaths were equal to an annual rate of 3·7 per 1000; among the various sanitary areas the lowest death-rates from these diseases were recorded in St. George Hanover-square, Westminster, Stoke Newington, Battersea, Lewisham, Woolwich, and Lee, and the highest rates in Marylebone, Islington, Holborn, Shoreditch, Bethnal Green, Poplar, St. George Southwark, and St. Olave Southwark. The 2 fatal cases of small-pox were within one of the corrected average number in the corresponding periods of the ten preceding years; 1 belonged to Lambeth and 1 to Greenwich sanitary areas. The 552 deaths referred to measles were considerably more than double the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Marylebone, Islington, Strand, Shoreditch, St. George Southwark, Rotherhithe, and Greenwich. The 69 fatal cases of scarlet fever were 8 above the corrected average number; this disease showed the highest proportional fatality in St. George-in-the-East, Mile End Old Town, and St. George Southwark sanitary areas. The 193 deaths from diphtheria were 77 above the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Fulham, Marylebone, St. Pancras, Clerkenwell, Shoreditch, St. George-in-the-East, Limehouse, and Camberwell. The 386 fatal cases of whooping-cough were 77 above the corrected average number; this disease showed the highest proportional fatality in Shoreditch, Bethnal Green, Limehouse, Poplar, Bermondsey, and Wandsworth sanitary areas. The 27 deaths referred to enteric fever were 8 below the corrected average number; the mortality from this disease showed no marked excess last month in any of the sanitary areas. The 32 fatal cases of diarrhœa were 23 below the corrected average number. In conclusion, it may be stated that the mortality in London during March from these principal zymotic diseases was more than 64 per cent. above the average.

Infant mortality in London during March, measured by the proportion of deaths under one year of age to births registered, was equal to 140 per 1000, and was below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in Hampstead, Stoke Newington, Strand, St. George-in-the-East, Lewisham, and Woolwich; and the highest rates in St. James Westminster, St. Martin-in-the-Fields, Clerkenwell, Bethnal Green, St. Saviour Southwark, and Newington.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-LIEUTENANT-COLONEL BLENNERHASSETT has joined the depôt of the Medical Staff Corps at Aldershot prior to his transfer to Netley as the successor of Brigade-Surgeon-Lieutenant-Colonel Evatt, who has embarked to take up the appointment of Principal Medical Officer at Hong-Kong. The following arrivals from abroad are notified:—Surgeon-Majors Archer, Donaldson, and Creagh from Bermuda; Surgeon-Captains Eckersley and Josling from Ashanti; Surgeon-Major Tidbury from Malta; and Surgeon-Captain Carter from Ceylon. Surgeon-Major E. Wilson has arrived at the Gold Coast on a tour of duty, and Surgeon-Major Hickman has been posted to the North British District. Surgeon-Colonel Preston will succeed Surgeon-Major-General Colahan as Principal Medical Officer in Ireland.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Captain Thacker, on arrival from England, is posted to the Bombay District, and Surgeon-Lieutenant Collins to the Mhow District. Surgeon-Major R. Cobb, Civil Surgeon of Patna, is appointed to officiate as Surgeon-Superintendent of the Presidency General Hospital, Calcutta, during the absence on furlough of Surgeon-Lieutenant-Colonel A. Crombie. Surgeon-Lieutenant-Colonel R. D. Murray, Civil Surgeon, Howrah, is appointed to officiate as Professor of Surgery, Medical College, Calcutta, and *ex-officio* First Surgeon to the College Hospital, during the absence on furlough on private affairs of Surgeon-Lieutenant-Colonel J. O'Brien. Surgeon-Major A. W. D. Leahy, F.R.C.S., Civil Surgeon, 24th Parganas, is appointed to officiate as Professor of Midwifery, Medical College, and Obstetric Physician, Eden Hospital, Calcutta, during the absence on furlough on private affairs of Surgeon-Lieutenant-Colonel C. H. Joubert. Surgeon-Major R. N. Campbell, M.B., is appointed to officiate as Senior Medical Officer, Port Blair, vice Surgeon-Lieutenant-Colonel D. P. MacDonald, M.D., who has been granted eight months' furlough on private affairs. Brigade-Surgeon-Lieutenant-Colonel G. Hutcheson, M.D., Bengal Medical Establishment, is granted the temporary rank of Surgeon-Colonel while officiating as Inspector-General of Civil Hospitals, Bengal, vice Surgeon-Colonel G. Ross, granted privilege leave. Surgeon-Lieutenant-Colonel P. J. Freyer, Bengal Medical Establishment, Civil Surgeon, Allahabad, retires from the service.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Deputy Inspector-Generals: G. Maclean to Hong-Kong Hospital and T. S. Burnett to Haslar Hospital. Fleet Surgeon John A. M'Adam to the *Victory*, additional, for the *Duke of*

Digitized by Google

Wellington. Staff Surgeons: George W. Bell to the *St. Vincent*; Charles W. Buchanan Hamilton to the *Penelope*, additional, for Ascension Hospital; and William G. K. Barnes to the *Australia*. Surgeons: Edward Cooper to Malta Hospital, Richard H. Way to the *Skipjack*, Frederick F. Mahon to the *Magpie*, and Ernest C. Lomas to the Portsmouth Division of Royal Marines. Surgeon and Agent: J. Cæsar to be Surgeon and Agent at Sheerness and Queenborough, in addition to Scrapsgate, East-end-lane, Leysdown, and Shellness already under his charge.

MILITIA MEDICAL STAFF CORPS.

William Kenneth Steele, gent., to be Surgeon-Lieutenant.

YEOMANRY CAVALRY.

Herts: Surgeon-Lieutenant L. Drage, M.D., to be Surgeon-Captain.

VOLUNTEER CORPS.

Artillery: 1st Norfolk (Eastern Division, Royal Artillery): Surgeon-Lieutenant R. B. Wrightson, M.D., resigns his commission. 1st Hampshire (Southern Division, Royal Artillery): Victor John Blake, M.B., to be Surgeon-Lieutenant. 1st Lincolnshire (Western Division, Royal Artillery): Lewis Walter Pockett, gent., to be Surgeon-Lieutenant. *Engineer: Fortress and Railway Forces, Royal Engineers:* 2nd Gloucestershire (the Bristol): Sidney Reginald Dyer, M.D., late Captain, to be Surgeon-Lieutenant. *Rifle:* 6th Volunteer Battalion the Royal Scots (Lothian Regiment): George Melville, M.B., to be Surgeon-Lieutenant. 1st (Cumberland) Volunteer Battalion the Border Regiment: Surgeon-Lieutenant J. Macdonald, M.D., resigns his commission. 1st Volunteer Battalion the Hampshire Regiment: Surgeon-Lieutenant J. W. Ekens resigns his commission. 2nd Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment): Surgeon-Captain A. Chawner to be Surgeon-Major. 2nd Volunteer Battalion the Loyal North Lancashire Regiment: Surgeon-Captain E. M. Garstang to be Surgeon-Major. 9th Lancashire: Thomas Wilson Banks, M.B., to be Surgeon-Lieutenant.

THE ITALIANS IN AFRICA.

It is announced from Rome, through Reuter's Agency, that in spite of the force occupying Kassala having recently defeated the Dervishes, Kassala is to be evacuated by its Italian garrison, and that, in accordance with General Baldissera's orders to that effect, Colonel Stevani is falling back upon Agordat, which is about half way between Kassala and Massowah. General Baldissera's action has been based upon the view he takes of the general situation. We learn also, from the same source, some interesting intelligence regarding the Red Cross Society. It appears that in consequence of the superabundance of aid at the disposal of the Italian Red Cross Society the German and Russian societies have been requested to suspend the despatch of nurses and material to Naples for service in Abyssinia. It is evident that some difficulty or hitch has arisen regarding the operation of these societies in connexion with the belligerent forces, for it is alleged that the Italian Government has addressed an inquiry to St. Petersburg regarding the names and position of the members of the Russian Red Cross Society who are to go to Abyssinia. The *Italie*, referring to the subject, says the Italian Government, in signifying its consent to the despatch of the Red Cross Mission, gave striking proof of its respect for the duties devolving upon all civilised Governments. "We hope," the journal adds, "that the Russian Government will, in its turn, recognise its duty to confine itself to a philanthropic and humane action, which can in no way give rise to an equivocal construction. Those whom Russia is sending to the Government of the Negus must obviously be only medical men and nurses; and it is for these that authority to pass through Massowah can be and should be granted. The Russian Government could not object to any decision which the Italian Government might feel compelled to take, if only out of regard for the very natural sentiments of the nation, which would never tolerate anything else being done under the guise of philanthropy."

ARMY MEDICAL SCHOOL, NETLEY.

The seventy-second or summer session of the Army Medical School, Netley, commenced on April 2nd. The following are lists of the surgeons on probation now attending the course of instruction:—

ARMY MEDICAL STAFF.

Names in order of merit.	London marks 4600.	Names in order of merit.	London marks 4600.

MORTALITY FROM FEVER AND "KALA-AZAR" IN ASSAM.

The mortality from fever has much increased of late in Assam, and a large portion of it appears under the head of "Kala-azar"—a parasitic disease attributable to the presence of the dochmius duodenalis. We learn that a medical officer is to be appointed to inquire into the subject and the causes of "Kala-azar." There seems to be some difference of opinion as to the exact nature of the disease which has given rise to the fever mortality in Assam—whether it is due to an aggravated form of malarial fever or to the parasite in question. It is quite probable that the two diseases may coexist; in other words, that the subject of a severe form of malarial fever may be also affected with the parasite. An investigation of the matter is likely to be of interest from a scientific point of view. Are the febrile phenomena and fatality traceable to the parasitic affection only or to the influence of malaria?

THE MEDICAL SERVICE IN INDIA.

Apropos of the proposed amalgamation of the Medical Services of Bengal, Madras, and Bombay into one Service, under the direct administration and control of the Government of India, to which we have previously alluded, the *Times of India* of the 14th ult. contains a paragraph to the following effect: "The Surgeon-General with the Government of India will be the head of the amalgamated Service, and his designation will be Director-General of the Indian Medical Service. No change will be made in the condition of the officers appointed before the second examination in 1896; but from that date the appointments will be made on one general list, and officers will be liable to an appointment in any part of India. The present surgeon-generals in Madras and Bombay will retain their privileges, but continuance of these privileges to their successors will be reserved for future consideration."

THE DEFENCE AND RELIEF OF CHITRAL.

We are extremely glad to learn that an Army Order has been promulgated at the War Office with reference to the grant of a medal and clasps for the defence and relief of Chitral. The order is preceded by another in which it is stated that the Queen has been graciously pleased to approve of a new medal—to be designated "the India Medal, 1895"—being struck to commemorate military operations on the frontier of India. This medal will have two clasps, for the defence and relief of Chitral respectively, which will be issued to the troops employed in the operations connected therewith between certain specified dates. Anyone may feel proud of having taken part in either the defence or relief of Chitral, and we are glad to think that some of the members of the two medical services did not play the least distinguished part in those operations where all strove to do their duty.

THE EASTER VOLUNTEER MANŒUVRES.

Some facetious individual has said that we do not have "weather" in England, but only samples, and the truth of his remark, if tested by the period during which the Easter Manœuvres have taken place, must be admitted. On the whole, however, the weather which prevailed has been as enjoyable as that which prevails at most Eastertides, and the Volunteers who took part in the operations may be said to have spent a profitable and useful holiday. Some 26,000 men must have left London for Folkestone, Canterbury, Eastbourne, Winchester, Brighton, Shorncliffe, Sandgate, and other towns where the manœuvres took place. The Medical Staff Corps were stationed at Walmer and were quartered at the barracks in that town. Among the officers were Surgeon-

Digitized by Google

Lieutenant-Colonel Norton, commanding, Surgeon-Captain Squires, and Surgeon-Captain Harper.

THE GOVERNMENT DAIRY AT ALDERSHOT.

Some discussion took place at the last meeting of the Aldershot district council as to the proposal of the War Office to establish a dairy on the Government sewage farm at Aldershot, whence the military will be supplied with dairy produce. The general opinion was that an individual would have to be appointed as the actual vendor of milk, &c., on behalf of the Government, and the dairy and such vendor would be liable to the restrictions and regulations applicable to private dairies. No action was therefore taken in the matter.

THE MATABELE RISING.

Amid the numerous wars and military operations that are taking place at the present time the news from South Africa occupies a fairly prominent position. There has been some sharp fighting in Matabeleland between the Hon. M. Gifford's party and the natives, in which this officer and some troopers have been wounded and a few killed. There is no doubt that the wounded will be well looked after.

THE PREVENTION OF CHOLERA AMONG THE COOLIES IN ASSAM.

The *Pioneer Mail* states that the plan suggested by the India Tea Association for guarding against cholera among the labourers intended for the Assam gardens is being tried in Calcutta, where coolies enlisted for the gardens are being inoculated by Professor Haffkine's method.

VOLUNTEER MEDICAL STAFF CORPS.

Her Majesty has been pleased to approve of the disbandment of the Norwich Company, with effect from March 31st, 1896, and Surgeon-Major T. W. Richardson is allowed to resign his commission from that date, with permission to retain his rank and to continue to wear the uniform of the Corps on his retirement.

DEATH IN THE SERVICES.

Surgeon-Major Arthur Francis Sargent, M.R.C.S., L.S.A., 3rd Bombay Infantry, at Nice, on March 27th, aged forty-three. He entered the Army as Surgeon on Oct. 1st, 1877, and was promoted to the rank of Surgeon-Major in 1889. During the year 1884 he served with the Zhob Valley Expedition.

Three hundred and eleven patients were admitted to the Royal Victoria Hospital, Netley, on April 2nd, *ex* steamship *Dilwarra* from Bombay.

Correspondence.

"Audi alteram partem."

THE TREATMENT OF HEART DISEASE BY BATHS AND GYMNASTICS.

To the Editors of THE LANCET.

SIRS,—In several of the articles recently published in the English medical journals on the so-called Nauheim treatment of heart disease I find that the meritorious work of the late Professor Beneke in this branch of therapeutics has not been sufficiently acknowledged, whilst that of another well-known physician of Nauheim—namely, Dr. Groedel—has not been even mentioned; and nothing has been said about the gymnastic treatment of heart diseases having been first employed in Sweden. I will therefore be greatly obliged if you will allow me to make the following remarks.

Beneke as early as 1859 and 1861 described the effect of the Nauheim baths on heart diseases. Special papers on this subject appeared in the years 1870, 1872, and 1875, in which we find that Beneke treated not only valvular lesions combined with rheumatism but all kinds of heart diseases, and I beg to call particular attention to the fact that he found that not only was a soothing effect produced by the baths upon the heart's action but that there was also a striking improvement of the compensation in cases where no other treatment had been of any effect. The next paper on this subject was written by Dr. Groedel in the year 1878 and appeared in the *Berliner Klinische Wochenschrift*, and this was the *first* announcement "that the baths increase the energy of the heart's action," an effect which was thus expressed in the first work of Dr. A. Schott two years later: "Baths are a first-class tonic for the diseased heart." A number of papers followed, written both by A. Schott and Groedel and subsequently by Th. Schott. Among those by Groedel I will only mention: The Effect of Baths on Respiration and Circulation,[1] the Treatment of Heart Diseases,[2] Nervous Heart Diseases,[3] Bad Nauheim and the Treatment of Chronic Heart Diseases,[4] a paper on the same subject in THE LANCET,[5] and Baths in Cases of Arterio-sclerosis.[6] As regards gymnastics for heart diseases Schott's first paper appeared in 1885. But publications by Swedish physicians about the application and advantages of gymnastics in disordered circulation are of much older date. Dr. Saetherberg of Stockholm, who made use of gymnastics for cardiac lesions as early as the year 1847, described his experiences in *Hygiea* in 1862, and he was followed in the same paper by Wrettind of Gottenburg in 1867 and by Dr. Zander in the *Nord. Med. Archiv*, 1872.[7] It is undoubtedly to the late Dr. A. Schott that we owe the first employment of gymnastics in cardiac disease in Nauheim, but the modifications made by him in the Swedish system were so insignificant that it cannot be called a method invented by himself. Groedel, who a year later published good results attained with gymnastics, prefers gymnastics with Zander's machines in certain cases to manual exercises.[8] I myself have also seen the best results produced by Zander's mechanical gymnastics.

Summing up all this, we find that Beneke having devised the bath treatment for heart disease, and Swedish physicians the gymnastics, there is no real reason for giving the name of Schott's method to the two treatments combined. Dr. Schott has endeavoured to explain the effects of baths and gymnastics, and in so doing he has assisted in making both methods of treatment better known, but others, especially Groedel, have also contributed to this end. In Germany, where the course of events could be followed from the very beginning, nobody ever thinks of speaking or writing about a "Schott method," we seldom hear even of a "Nauheim method," but simply of Nauheim as a health resort for patients with heart disease.

I am, Sirs, yours faithfully,

DR. HERMANN NEBEL,
Physician and Specialist for Gymnastics at Frankfort.

Frankfort-on-the-Maine, April 2nd, 1896.

*** We are much obliged to our correspondent for recalling the work of Professor Beneke and Dr. Groedel to our recollection. In THE LANCET of Dec. 22nd, 1894, page 1515, there is a letter from an Eastbourne correspondent of a tenour somewhat similar to the above, in that it asks for justice to the claims of Sweden as the original home of the essential part of the treatment.—ED. L.

THE EFFECT OF MUSCULAR WORK UPON THE ALKALINITY OF THE BLOOD.

To the Editors of THE LANCET.

SIRS,—Although my knowledge of the subject is scarcely such as to entitle me to speak, you will, perhaps, allow me to compare the statements made in two articles which appeared in THE LANCET of March 7th with regard to the effect of muscular work upon the alkalinity of the blood. In the course of his most interesting contribution upon the effect of exercise on the secretion of urea Dr. Haig, referring to the chapter on Mental Depression and Fatigue in the second edition of his book, "Uric Acid," observes: "I then go on to point out that the effect of exercise is to lower the acidity of the urine owing to the increased excretion of acids by the skin in perspiration; that the fall of acidity, or, more accurately, the increased alkalinity of the blood, allows the passage of an excess of uric acid through it, and that this is accompanied by a fall of urea and the presence of more or less marked feelings of fatigue." Upon this assumption that the effect of exercise

Digitized by Google

is to increase the alkalinity of the blood is based Dr. Haig's entire theory of the cause of fatigue—a theory that seems to be completely borne out by the experiments he adduces. But in the article which follows, "The Clinical Estimation of the Alkalinity of the Blood," Dr. Hutchison makes the following explicit assertion: "The effect of severe muscular work is to cause a fall in the alkalinity of the blood, this being probably due to the production of considerable quantities of lactic acid by muscular metabolism." How can these two statements be reconciled? Dr. Haig, it will be seen, attributes the rise in the alkalinity to the increased excretion of acids by the skin, while Dr. Hutchison thinks that the reverse result is probably due to the production of lactic acid by muscular metabolism. Which is the correct view? As I have said before, I can lay claim to absolutely no qualification that would entitle me to express any opinion upon the subject, but the question as to what really is the effect of muscular work upon the alkalinity of the blood is one of such great interest and importance that I may possibly be excused for calling attention to it in this instance. I am, Sirs, yours faithfully,

March 16th 1896. W. B. FOTHERINGHAM.

"THE NEW INFANTRY SWORD EXERCISE."

To the Editors of THE LANCET.

SIRS,—In a letter published in THE LANCET of March 28th Dr. Ritchie takes exception to my criticisms,[1] founded on anatomical and physiological grounds, of the new infantry sword exercise. With your permission I will reply briefly to the points he raises. I endeavoured to show that in the Masiello system—a more accurate term, I understand, than "Italian" for the newly-adopted exercise—a greater expenditure of force is necessary to effect the required movements than in the French system; that fatigue, in consequence, will ensue earlier; that the chief muscles concerned have to act at an undue mechanical disadvantage; and that rapidity, variety, and delicacy of movement are to a great extent sacrificed in order to ensure a more powerful thrust. It does not appear to me that Dr. Ritchie effectively traverses these propositions. With regard to the "on guard" position, Dr. Ritchie argues that the wider separation of the feet in the Masiello attitude allows greater rapidity in the "advance" and "retire," because a greater pressure can be exerted in the left foot in the "advance" and from the right in the "retire." I cannot agree with him. The more the feet are separated the greater is the exertion necessary in the initial stage of either movement and the less perfect is the balance. Additional exertion is therefore required to preserve the balance. If we accept Dr. Ritchie's view it should follow that with the feet still more widely separated than is prescribed in the Masiello "on guard" position the movements of "advance" and "retire" are still further facilitated. We are then brought face to face with a very obvious *reductio ad absurdum*. Dr. Ritchie admits frankly the greater exertion needed when he writes that the advantage of "greater rapidity of movement backwards from the Italian than from the French attitude" (retiring) is "well worth the extra effort entailed by the further separation of the feet." But to my mind the removal of the resistance of the left foot in retiring leads not to greater rapidity of movement so much as to loss of balance. The further the supporting leg (in this case the right) is from the line of gravity passing through the trunk, the less perfect is the balance and the greater is the effort required to maintain it. Comparisons of diagrams of the Masiello and French attitudes will make this point obvious at once. The greater the exertion the more quickly will fatigue ensue.

Next, as to recovery from the lunge, Dr. Ritchie considers that the raising of the body to the vertical position is effected by the hamstring muscles rather than by the gluteals, as I stated. I think this criticism is sound. I noticed the error before my letter appeared in print, but when it was too late to correct it. The correction makes my case stronger. It is unnecessary for me to call attention again to the mechanical disadvantage under which the hamstring muscles act and the disproportion between the two arms of the lever, for Dr. Ritchie himself points this out very clearly. As the muscles act at such a mechanical disadvantage the expenditure of force necessary to effect the recovery is very great, far greater than in the recovery from the French lunge. And for the same reason the initial velocity of the backward swing is comparatively low. By "backward swing," it must be noted, is meant the raising of the body from the inclined position forwards to the vertical attitude; beyond this the body is not allowed to swing. The chief function of the erector spinæ in this action is to preserve the rigidity of the longer arm of the lever. To the opinion that the backward swing does not increase the rapidity of recovery I must still adhere. The experiment mentioned by Dr. Ritchie only illustrates the greater force needed in recovery from the Masiello lunge. The extra exertion and the consequent fatigue again are practically conceded. Dr. Ritchie makes no allusion to the fatigue entailed on the sword arm by the extended position of the limb in the "on guard" position, and I may take it, therefore, that he concedes this point also, which, indeed, it seems impossible to question. He does not deal with the remarks I made on the movements of pronation and supination on the ground that in the Masiello system these movements are not concerned, supination being only required in one of the parries; that is to say, that all the advantages to be obtained in the French system from the various movements of the fingers and the actions of pronation and supination are thrown away in the Masiello method. The greater variety of movements, and the fact that they can be made with less expenditure of force and so entail less fatigue, seem to me, on anatomical and physiological grounds, to make the French system incomparably the more scientific of the two. I am, Sirs, yours faithfully,

Brook-street, W., April 6th, 1896. C. T. DENT.

[1] THE LANCET, Nov. 30th, 1895.

THE SANITARY INSTITUTE AND THE ISOLATION OF CASES OF INFECTIOUS DISEASE IN THE METROPOLIS.

To the Editors of THE LANCET.

SIRS,—The interesting paper on the above subject read at the sessional meeting on March 11th by Mr. Augustus Charles Scovell could not have failed to impress the audience with the importance of this subject as regards the protection of the public against zymotic diseases and consequently the reduction of the death-rate. But while I deeply appreciated the interesting discussion and the important contribution thereto by the eloquence of Dr. Thorne Thorne I was disappointed that little or nothing was said as to the working of the Notification Act. My presence as a guest made me feel some diffidence as to the etiquette of personally calling attention to the subject, the importance of which alone justifies my now drawing attention to it. Mr. Scovell, in speaking of scarlet fever in connexion with the future demands for hospital accommodation, said that "the accumulating statistics of notification ought to prove useful." And it is to this disease alone that I shall confine my comments. Mr. Scovell is right, but I feel sure as long as the Act remains as it is, and as long as even its present provisions are not strictly carried out, the Metropolitan Asylums Board will not benefit by the collected statistics as much as they desire, nor will the disease become less prevalent; nay, even the contrary effect will be produced. I am confident that the Act is not thoroughly carried out and that it wants amending so that the full benefit it was intended to convey to the public may be secured. I would ask, first, why is the Act not strictly carried out? and, secondly, what defect, if any, conduces to render it incompetent to deal with this disease as we all desire?

Now, Sirs, in answer to the first question I would say that the Act places a penalty on the head of the family which might become so severe that he deliberately, and perhaps not unnaturally, tries to avoid coming under its provisions; and owing to the notification having in many instances to go to an opposing general practitioner it is felt to be a grievance in provincial towns—where there is much prejudice against employing a medical man who is known to be in attendance on a patient suffering from an infectious disease—that one practitioner should be placed in possession of information that sooner or later leaks out (not by the medical officer of health divulging information he has officially received) and which will bring temporary loss on the notifying practitioner. That part of the question relating to the head of the family is by far the more serious. No medical man would abstain

Digitized by Google

from notifying a case of the diagnosis of which he was confident; and parents know this, so that in times of epidemics, large or small, the medical man is not sent for until some serious complication has arisen. The latter may then feel morally certain that the patient's symptoms are the sequelæ of scarlet fever, but when he is met by a negative reply to all his definite questions he may well be excused, with legal actions so prevalent, if he lets the matter drop, contenting himself with treating the present symptoms. I do not imply that honourable members of the profession, when once satisfied as to the nature of the case, would even let this fear stand in the way of duty; but I do assert that the case of a large tradesman whose keenest opponent in the trade is on the sanitary board and whom publicity of the fact of there being fever on his establishment will affect seriously (added to the fact that he is a constant and good all-round patient of the medical man) presents a combination of circumstances that may enable the medical man not to be reasonably satisfied that he has a case of scarlet fever to deal with. And in the case of the lower classes a more painful and a sadder state of things confronts the medical man. He sees a case and informs the parent it must be notified, which means that no children must go to school, causing a prolongation of the time before A and B can pass the necessary standard and take their part as partial bread-earners of the family. A and B, too, who get 2*s*. a week each and their breakfast by cleaning boots and knives before going to school, must relinquish this work for several weeks. The mother must not go out charing, &c. Is it surprising, then, that among this class the medical man rarely sees the rash or any other early symptoms? Hundreds of cases are so mild that the little patients have no medical attendance, and when they do it is for scarlatinal nephritis, dropsy, or some other sequel which has frightened the parents. The tale is always the same: they have seen no rash, noted nothing, know of no adjacent cases, and even when the desquamating parts of the body are pointed out the utmost surprise is expressed and the medical man is asked if he is certain of his diagnosis.

The answer to the second question is brief. Let the Act be so altered or amended that no general practitioner shall be eligible for the post of medical officer of health. Let an indemnifying clause be added to protect all practitioners from the annoyance of any legal action consequent on the notification of cases of infectious disease, and give protection to the public in case of their disputing the diagnosis by empowering them to demand a consultation with the medical officer of health free of charge. Make it a good action at law for libel for any member of a sanitary board to divulge information obtained under the Act; and, most important of all, insert a compensation clause so that parents shall not suffer pecuniary loss by having to isolate the sick child as well as other members of the family. I am confident with this clause every member of the community would help the profession to stamp out the disease, instead of as now spreading it far and near. Let the poor man lose nothing by the isolation of the little patient and his whole family and he will help in the matter. Increased hospital accommodation would not be necessary, and I feel sure that highly satisfactory results would shortly be obtained.

I am, Sirs, yours faithfully,

ELLIOT DAUNT, L.R.C.P.Lond., M.R.C.S.Eng., D.P.H.

March 23rd, 1896.

"DEATH UNDER CHLOROFORM AT A DENTIST'S ROOMS."

To the Editors of THE LANCET.

SIRS,—The reasons for avoiding the sitting posture for the patient in the administration of chloroform have not, I think, been recently given.

It is clear from the exhaustive experiments of Dr. Leonard Hill[1] and of the Hyderabad Chloroform Commission[2] that the force of gravity has a marked effect upon the circulation, especially under the influence of certain anæsthetics, producing a fall of blood pressure in the carotid arteries in the vertical and sitting postures, which can be restored by placing the body in a horizontal position; also, that when the compensatory vaso-motor mechanism of the splanchnics is paralysed the sitting posture is dangerous, because it allows dilatation of the abdominal veins, emptying of the right heart, and failure of the cerebral circulation.[3] Now chloroform lowers the blood pressure and rapidly paralyses the splanchnic vaso-motor mechanism. It cannot, therefore, be safe (with our knowledge of the limits of chloroform anæsthesia) to add the lower blood pressure of the sitting posture to the lowered blood pressure and paralysed vaso-motor mechanism of chloroform narcosis.

Beside these considerations the mortality from chloroform in any position is five times that of ether.[4] Nitrous oxide and ether cause a rise of blood pressure and do not readily paralyse the splanchnics even in large doses; they can be administered together or ether can be given alone by means of Clover's inhaler, and will yield complete, quiet anæsthesia of any required duration without danger in the sitting posture. This is a matter of every-day experience, supported by all the above experiments and authorities. For these reasons—and I write in the hope that they may be more widely recognised among dental operators—I would urge very earnestly that it is not justifiable to administer chloroform for dental operations when ether can be obtained, unless the patient is prepared beforehand, laid flat upon a couch, and the risks are clearly recognised as in all sugical procedures. In my opinion cases obliging the use of chloroform in dental work are extremely rare, and if they do arise the risk to life will be reduced by such precautions.

I am, Sirs, yours faithfully,

H. BELLAMY GARDNER,

Assistant Anæsthetist to Charing-cross Hospital and to the Dental Department.

Welbeck-street, Cavendish square, W.

"THE DUTIES OF DIVISIONAL SURGEONS IN CASES OF INFECTIOUS DISEASES."

To the Editors of THE LANCET.

SIRS,—Mr. Harnett's letter is no answer to my inquiry, although he admits the two flagrant breaches of professional etiquette I specified. I regret to see no word of apology. Whatever he may write to the contrary, I emphatically deny having ever given him any cause for his behaviour. I am not aware that a *tu quoque* argument exonerates a man from following the well-established rules which govern the behaviour of one professional man to another. I propose to adduce several other instances of similar misconduct occurring in my practice that your readers may judge of this gentleman's procedure. Some months ago a mild scarlet fever epidemic existed here and attacked several families of the police force. In one instance the father was told to have the patients' heads shaved or cut close. This was objected to and the divisional surgeon reported the man to the inspector to enforce his prescription. It appeared to be *ultra vires*, however, and was dropped. In another instance the divisional surgeon ordered the family out into the garden at the end of a fortnight—at least, so the mother told me. I was also told that the inunction of a medicament which I had ordered had not the sanction of his approval. In a case of diphtheria the divisional surgeon got the child out of bed and made it walk to the window that he might examine the throat—surely an unnecessary punishment for being the patient of another practitioner. When this uncalled-for and irritating interference is indulged in on every possible occasion it indicates to my mind an animus which must be destructive to a man's judgment on other matters. Other divisional surgeons whom I have consulted disclaim any mission to offend professional propriety and have no such difficulties. The limits of my letter will not permit me to discuss the irrelevant matter and inaccuracies introduced into Mr. Harnett's letter. As there is no promise of amendment I shall consider it my duty for the protection of my patients and myself to call the attention of the Chief Surgeon of Police to this correspondence in the hope that Mr. Mackellar may be able to render the divisional surgeon's self-imposed duties less onerous. It is not my intention to prolong this correspondence further.

I am, Sirs, yours faithfully,

Barnet, Herts, April 6th, 1896. W. THYNE, M.B., C.M. Edin.

ACUTE CONGESTION OF THE LUNGS (?).

To the Editors of THE LANCET

SIRS,—Dr. Squire, in his interesting and instructive paper on "Some Clinical Remarks on Pneumonia," published in THE LANCET of April 4th, says, "It is an interesting point whether there are cases which justify a diagnosis of acute congestion of the lung." A case which has quite recently come under my notice seems explicable only on the assumption that such a pathological condition as active pulmonary congestion does exist. A girl aged eighteen years, who had been suffering from obscure pains in the limbs for some days previously, was suddenly attacked with dyspnœa, shivering, and cough. When seen there was loss of resonance over the lower third of the right lung, and over this same area crepitations, fine consonating râles, and tubular breathing were well marked. Vocal fremitus was not increased, nor could bronchophony be heard. The temperature was 101·9° F. Respirations were increased in frequency and the cough was very troublesome. Next day the patient expressed herself as feeling much better. The area of dulness was diminished, and by the end of forty-eight hours the right lung was quite resonant and the breath sounds had assumed the normal vesicular tone. The cough still continued and the expectoration was profuse. The morning and evening temperatures were normal, and the patient has made an uninterrupted recovery.

I am, Sirs, yours faithfully,
J. H. MARSH,
April 7th, 1896. Senior House Surgeon, The Infirmary, Macclesfield.

"THE QUESTION OF MEDICAL DEFENCE."

To the Editors of THE LANCET.

SIRS,—Now that there seems to be a general desire that we may make the Medical Defence Union a strong corporation to defend the individual rights of its members, I think many medical men would join if an undertaking was given that they would not interfere in disputes affecting personal matters between medical men. I know of a case where one medical man, a member of the Union, slandered a medical man who was not a member simply because he started a practice for himself without purchasing it, and on the writ being served it was immediately taken up by the Union. Is this fair play?

I am, Sirs, yours truly,
March 24th, 1896. PERPLEXED.

DEATH CERTIFICATES FOR TONTINES.

To the Editors of THE LANCET.

SIRS,—A man whose child dies comes to Dr. A—— for a certificate of death, which is given on the usual form for the registrar. The father being in a tontine society is entitled to £1 on the death of his child, and he therefore asks for other certificates so as to obtain this money. Dr. A—— writes out (on note-paper) a certificate as required. The registrar on being informed of this states that the payment of the money on such a certificate is illegal. Would you kindly inform me whether this is correct?

I am, Sirs, yours truly,
April 7th, 1896. A. M.

*** Section 14, Sub-section 2, Friendly Societies Act, 1875, says: "No registered society shall pay any money on the death of a person of any age without the production of a certificate of the death issued by the *registrar or other person who has the care of the register book* in which the death is registered." It will therefore be seen that the registrar is legally right, but we do not admire the by-law that places the medical man in this position.—ED. L.

THE LANCASHIRE ASYLUMS BOARD'S PENSION SCHEME.

To the Editors of THE LANCET.

SIRS,—Few will be found to congratulate the Lancashire Asylums Board on their recently formulated pension scheme. It is to be hoped that the scheme is but a tentative one, as in its present form it is in most respects extremely imperfect. Possibilities there are, truly, but certainties none. The earnest, faithful asylum official has been led to expect, after a period of from twenty to thirty years of difficult, often dangerous, and comparatively ill-paid service, a definite pension according to his service and record. It is well known that the promise of this pension was taken into account when the various salaries and values of the emoluments were fixed. Now, forsooth, he may obtain, irrespectively of his record of good and long service, between fifty-five and sixty years of age, a pension of at least one-third of his actual salary or at most of two-thirds of his salary and emoluments, but the actual amount of which depends upon the caprice or temper of the awarding body which may then be in office. Several instances have lately occurred where the amount of an attendant's pension proposed by the committee of visitors of the asylum to which he belonged has been cut down to one-half by the Asylums Board at the general meeting by a majority of members who, knowing nothing of the merits of the case, yet so voted either out of jealousy, a feeling of economy, or a rooted aversion to any pension scheme whatsoever. Even apart from these wide limits the scheme is too elastic, every provision being so arranged as to be possibly set aside or to be modified indefinitely. The minimum age at which a pension may be ordinarily granted is fixed by the Lunacy Act of 1890 at fifty years, yet this is over-ridden and other five years added in this scheme, making the minimum age fifty-five years. The age for compulsory retirement proposed in this scheme is sixty years. Few attendants on the insane are fit for active duty after fifty-five years, as long service in an asylum has without doubt a markedly deteriorating effect both mentally and physically.

One could name several counties, some of far less extent and importance than Lancashire, where definite and equitable pension schemes have been adopted and which have given general satisfaction. I am, Sirs, yours faithfully,
April 4th, 1896. LANCASTRIAN.

A MEDICAL OFFICER OF HEALTH AND THE LONDON COUNTY COUNCIL.

To the Editors of THE LANCET.

SIRS,—I should be obliged if you would give me an opinion on the following case. The solicitors of the London County Council have entered into correspondence with me and have got me to call and see them in their office at Spring-gardens. The letters and interview relate to a scheme of the Council relative to an insanitary area (Falcon-court, Borough, Southwark) under Part II. of the Housing of the Working Classes Act, 1890, a portion of the expenses in the carrying out of which the vestry of St. George's, Southwark, have agreed to pay. I am asked by the Council to (*a*) draw up death-rates, births, &c., for the past four years and make up a full report of evidence; and (*b*) to give evidence before a public inquiry, which is shortly to be made by the Local Government Board to support Dr. Hamer's evidence. The area in question is in St. George's, Southwark, for which I am "*wholetime* (?)" medical officer of health, and I have received the consent of my authority to give the evidence. I wish to know whether I would be justified in charging the London County Council a fee for the evidence and for the report of evidence, &c., drawn up in the evenings after office hours, or must I give my services gratuitously? Nothing so far has been said about any payment by solicitors or self. Some time ago I was similarly interviewed by the London County Council solicitors and asked to give evidence on (*a*) Water Bills of the London County Council, and (*b*) the amount of water necessary to flush w.c.'s. The first thing I did on calling upon the London County Council solicitors was to ask them on what terms I was to give evidence. They said *gratuitously*, and I accordingly refused the honour.

I am, Sirs, yours faithfully,
March 28th, 1896. M.O.H.

*** Our correspondent does not tell us whether in connexion with (*a*) the Water Bills of the London County Council and (*b*) the amount of water necessary to flush w.c.'s, he was asked by the Council or his own vestry to give evidence, but if the former this is the first instance of which we have heard in which the Council has refused to pay its medical witnesses. In reference to his question as to whether he would be justified in charging a fee for evidence, &c., in connexion with the

Digitized by Google

Falcon-court Scheme we think the only objection which could be raised to such action would be that his fee would be part of the expenses of the scheme, a portion of which would be paid by his own authority. We think he would do well to obtain leave from his authority to make a claim before doing so.—ED. L.

"ASSISTANTS."

To the Editors of THE LANCET.

SIRS,—Surely it cannot be maintained that the singularly unfortunate experiences of "A Sorely-tried Principal" are by any means those of the majority of medical men requiring assistance. The many difficulties with which an assistant has to contend have already been so ably dealt with by your two correspondents on this subject in THE LANCET of March 28th that it is quite unnecessary to again refer to them. I would wish, however, to emphasise the question of salary as being of still more importance. It cannot be expected that men of experience, possessing good diplomas and excellent references, will undertake to perform the often laborious and in many cases most irksome duties of assistant at the miserable salary of £6 or £7 (in-door) per month. Luckily, we junior members of the profession are not entirely dependent on these positions, and such salaries will be accepted only, I imagine, either by those but just qualified or who, by reason of intemperance &c., are unable to obtain more lucrative employment. I have always been taught that to obtain a first-class article one must go to a first-class firm and pay a first-class price. I would venture to say that if those requiring help were to adopt this principle there would seldom be grounds for such complaints as are the subject of "A Sorely-tried Principal's" letter.

I am, Sirs, yours truly,

April 6th, 1896. COUNTRY ASSISTANT.

P.S.—Would it not be interesting to know how many men and of what class will be attracted by an advertisement which offers the remunerative (!) salary of £20 (in-door) per annum?

THE BATTLE OF THE CLUBS.—XXVII.[1]

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 955.)

LEICESTER AND WOLVERHAMPTON.—THE POLICY OF THE MEDICAL UNIONS RECENTLY CONSTITUTED IN THESE TOWNS.

THE Medical Union movement is spreading in all directions. During the last few weeks it has been more particularly pronounced in the Midland counties. We have seen how a union has been successfully formed at Nottingham, and now we have to congratulate the profession on the constitution of similar organisations at Leicester, Wolverhampton, and Walsall. At Leicester the medical practitioners have been acting with marked circumspection. A meeting, to which all the members of the profession were invited, was held some time ago and was well attended. A union was then constituted, but it was decided to study the situation thoroughly before taking action. From the first it was evident that the position and the interests of the medical men concerned differed very widely. To discuss in common the various phases of contract or club work would occasion a great loss of time. The contract work at Leicester may be divided into three or four categories. First of all there are the twenty-seven practitioners who are attached to the Leicester Provident Dispensary. Then there are the medical officers of the friendly societies and the medical officers in the service of insurance companies. To these three categories may be added the medical men who have private medical aid dispensaries of their own. Instead of holding large meetings in which all these different questions would be treated at once a number of small meetings have taken place. Thus the Provident Dispensary medical officers have met separately and several times. The same may be said of the other two categories: the insurance company medical men and the friendly societies' medical men. When in each of these branches the practitioners concerned shall have thoroughly investigated their own position and agreed as to the possible remedies, then the whole of the profession will be brought together again. It will then be decided whether a general effort can be made along the whole line or whether the grievances shall be fought out in detail, one at a time. If so, the point of least resistance will naturally be selected for the first attack. But in so large a town as Leicester, where the problem is so complex and differs according to the various institutions, a great deal of investigation and study is absolutely necessary before a policy of action can be safely pursued. Till this policy has been definitively adopted, and till the information and the means of action have been collected and organised, the Leicester Medical Union is wisely observing a prudent silence. There is no desire to rush into print till everything is ready, but in due time there is no doubt that a good case will be put before the profession and the public and that this statement will be followed up by energetic and, let us hope, effectual action.

At Wolverhampton there used to be a medical society which collapsed from inanition some ten years ago. It was, however, reconstituted in 1894 and called the Wolverhampton and District Medical Society. It was a scientific and social society—perhaps more social than scientific. In any case it served the primary purpose of bringing medical men together. Out of the fifty borough and thirty district practitioners thirty-two were enrolled as members of this society. On Feb. 12th last, when the members of this society met, a circular received from the Incorporated Medical Practitioners' Association occasioned some discussion on the grievances arising from club practice. Dr. Armitage spoke of hospital abuse and of the competition of medical aid societies. Dr. Malet admitted the prevalence of hospital abuse, but they could not be too severe as it was so difficult to collect funds for the maintenance of in-door patients. The general consensus of opinion gravitated towards the suggestion that a provident institution managed by the medical profession should be established at Wolverhampton on somewhat similar lines to what has been done at Eastbourne. A resolution was carried to the effect that information should be obtained as to the constitution and rules of those provident institutions which had been organised in other towns by the medical profession. This information having been secured, another meeting was held on March 11th, at which Dr. Deanesley moved and Dr. Malet seconded:—

"That in the opinion of this society it is advisable to establish in Wolverhampton a provident medical association (similar to that founded at Eastbourne) for the purpose of enabling those persons who cannot afford medical attendance at the usual charges to obtain the same under conditions satisfactory both to themselves and to the medical profession."

This was carried unanimously, but the attendance was small and limited to the members of the society. It was therefore resolved that a general meeting should be convoked and all the members of the profession invited to attend. Together with this invitation a copy of the Eastbourne rules was forwarded to every practitioner. On the invitation the text of the above resolution was given, with the intimation that it would be submitted anew to the general meeting by Dr. Armitage and seconded by Dr. Bankier in order to ascertain whether the general body of local practitioners were willing to coöperate with the medical society in carrying out the proposed scheme. This general meeting took place on March 25th, and twenty-eight out of the fifty borough practitioners attended. Six other practitioners wrote letters of approval. It may be said that two-thirds of the local practitioners are in favour of the

Digitized by Google

scheme. Among the remaining third there is little or no active hostility, but mere lukewarmness. Most of the speakers were in favour of following the Eastbourne example, which had been rendered familiar to the members present by the full description published in the columns of THE LANCET. The speakers denounced the sweating of the medical profession, the lay control of medical work, the absence of a wage limit, and generally agreed as to the prevalence of the various grievances that have so frequently been exposed in this series of articles. One medical practitioner who was recently in the service of the friendly societies said he was at first opposed to the scheme because he thought that persons who could afford to pay small bills would be tempted to join an institution which the medical men themselves had organised, though they now objected to belong to the clubs or medical aid associations managed by laymen. This objection, however, would be met if a wage limit was enforced, particularly if that limit was not too high. Another speaker also feared that the creation of a provident association by the profession would tend to increase instead of reducing the prevalence of club practice. Such a provident association being supported by the whole of the profession would acquire so high a reputation that private patients would be tempted to join. Then, again, there are at Wolverhampton several practitioners who compete successfully against the clubs by adapting themselves to the needs of the working classes. Thus, when there is serious illness they undertake the charge of the case for a fixed sum, perhaps 7*s.* per week. Others maintain the 2*s.* 6*d.* fee, but they forget to charge for every other visit. Their attendance by these means does not cost more than workmen can afford. Nor, apparently, is the average cost to the workman greater than if he paid 1*d.* per week whether well or ill. In any case many workmen prefer this system to joining a medical aid club. The medical men who do this sort of practice fear, however, the probable competition of a provident society organised by the profession. Nevertheless, here again the difficulty resolves itself in the establishment of a wage limit, which, however, it is urged should be lower for Wolverhampton than for Eastbourne. When the resolution as above was put four hands only were held up in opposition. Two of these voters were the medical officers who are engaged at a fixed salary by the amalgamation of the friendly societies. One of them rose and delivered a denunciatory speech. He complained that the movement was simply an attempt to form a capitalist "ring." This association of the privileged and more fortunate members of the profession would have for policy the boycotting of medical men, who were none the less brothers in the same profession, because they were so poor that they could not sit still and wait for a practice, but were compelled by the necessity of existence to accept posts at fixed salaries in the service of friendly societies. The suggestion that a medical society which is composed in part of medical men who are in a necessitous position and have to work very hard for a modest income could be qualified as a "ring" of capitalists excited a good deal of laughter. Nevertheless, the medical profession will have to deal with the unemployed question, for it is the principal obstacle to successful organisation. A very active local practitioner with whom I discussed the Eastbourne scheme said that at Wolverhampton the profession might be divided into three categories. First, there was the young medical man who had very little work; secondly, there was the consultant; and, thirdly, the busy general practitioner. If the profession established a provident association of their own the consultant would not lose anything. The young practitioner by inscribing his name as one of the active medical officers of the association would gain a great deal. Also, was there not a risk that medical men of somewhat inferior reputation would profit by the opportunity to put their names down side by side with those who enjoyed the highest reputation and profit undeservedly by such a juxtaposition? In conclusion, he thought that the general practitioner who had many patients was likely to lose by the arrangement. Also he thought that in Wolverhampton many medical men were so lax in the observance of medical etiquette that he failed to see what guarantee there could be that the rules of the proposed provident association would be strictly observed by its active medical officers. Of course, the wage limit and the uniformity of charge form the sovereign remedy for all these doubts. As this charge would be paid to the society and not to the individual medical officers it is difficult to see how the latter could undersell each other. But the very fact that so many criticisms were made led me to the conclusion that the Wolverhampton Medical Society had, perhaps, been attempting to run before it had learnt how to walk. It also struck me that there was a tendency to put all the eggs in one basket. The formation of a provident association such as exists at Eastbourne is, after all, only one phase of the struggle, and the position of affairs is much more simple in a small fashionable watering-town than in a working-class and manufacturing community like that of Wolverhampton. Above all, there is always a tendency, all the more dangerous as it is most natural, to hasten to grapple with the evil. The desire is to at once engage in a heroic battle and win a glorious victory. The patient, slow, laborious work of organising such armies as alone can win battles is not so attractive, especially to such busy men as medical practitioners. Yet without very careful organisation disasters are likely to ensue, followed by discouragement and disbandment. It seemed to me very evident that at Wolverhampton schemes of action had not been maturely studied. The Union, such as it is, is not yet sufficiently strong, and it has only discussed the question of forming a provident association on the Eastbourne model. Will the working men readily give up the management of the medical aid organisations which they have built up step by step and to which poor men have devoted hours of gratuitous labour? An elaborate and carefully prepared argument must be drawn up by the Medical Union and submitted to these workmen, so that they may be convinced that the medical profession is not acting against but in favour of their true interests. All this takes time and much study. Institutions which have grown up in the course of years are not overthrown in a day. The formation of a medical union is all the more creditable to those who succeed in bringing it into existence as it can only be firmly established by much laborious and persistent work. It redounds to the honour of the medical profession at Wolverhampton that they should have courageously attempted this arduous task. They have, perhaps, sought to advance a little too quickly at first; but if this is a mistake it is also a proof of zeal, and if the willingness to act is there, experience will soon show which is the right road to follow.

That action is necessary the deplorable state of affairs at Wolverhampton amply proves. These evils have been denounced over and over again. Dr. Leslie Phillips called attention to this town some four years ago. He then related, and the facts were printed at the time, that Mr. Wallington had been for five and a half years senior medical officer of the Wolverhampton Friendly Societies' Medical Association. For a salary of £250 a year Mr. Wallington went through the terrible excess of work occasioned by the first two influenza epidemics. He asked for some compensation, especially as he had incurred a considerable excess of cab hire. The income of the association at that time was £1835, out of which the medical officers and locum-tenents obtained only £498. Nevertheless, the association refused to pay the cost of the cab hire, and out of his modest income of £250 Mr. Wallington was out of pocket £57 for this item alone. While the association refused to bear this extra expense caused by the epidemic the profit they made was sufficient, after paying all working expenses, to purchase and pay for land to the value of £550. It was also calculated that the actual cash paid to Mr. Wallington only amounted to 10*d.* per year per member of the friendly societies. In 1894 this association had 8759 members. Its receipts had fallen to £1369, and out of this sum it paid its medical officers £425. On questioning some of the medical men who attend the members of friendly societies they admitted that some of the lady patients wore silk dresses and sealskin jackets. There is no doubt that the usual abuses prevail at Wolverhampton as in so many other towns. The disunited condition of the profession has up to quite recently been the chief obstacle to reform. As one practitioner observed in my presence, the medical men injure each other quite as much as the clubs injure them. It is not only advisable to establish a provident medical association which, under the management of the medical profession, shall replace the existing clubs and medical aid associations, but it is necessary also to fix a minimum limit which every medical man in competing with other medical men shall be bound to respect.

A HASTINGS DISPENSARY WOUND UP.

At a meeting held at the Hastings Town Hall on Monday, Dr. B. H. Allen presiding, it was resolved on the motion of

Digitized by Google

the Chairman, seconded by Mr. Coleman, that the Provident Dispensary be wound up.

THE PROPOSED CHEAP MIDWIFERY FEES AT LINCOLN.

To the Editors of THE LANCET.

SIRS,—There surely must be some explanation of the absurdly low midwifery fees which the union of medical men at Lincoln has gone in for. Read as the "Battle of the Clubs" doubtless is at this particular epoch by the officials of the various clubs, dispensaries, &c., it will be "nuts to crack" for them to find at what low fees the Lincoln medical practitioners assess themselves. It is, moreover, manifestly worse to demand such disproportionate midwifery fees than (under pressure) to accept them. If the worry and trouble of forming a medical union only eventuate in "half-guinea midwifery" all one can say is that "the game is not worth the candle," and that it is but another instance of *parturiunt montes, nascetur ridiculus mus*. Here (a Midland town which must perforce be nameless) no contract midwifery work is taken even now under 15*s.*, and in the case of the Oddfellows £1 1*s.* is the fee for attendance on primiparæ. Beyond and above all this, at various meetings of the profession in this town it has been all but unanimously agreed to that no midwifery case in any club or dispensary should be attended for a less fee than £1 1*s.*, and there is absolute unanimity that that should be the minimum fee for primiparæ.

Now the low midwifery fee which the Lincoln practitioners have announced—viz., "confinements 10*s.* 6*d.*, operative midwifery 15*s.*"—will have a tendency to lower the contract midwifery fee to be demanded by the various medical unions throughout the country, for how can medical men "in union welded" demand (I beg pardon, "suggest") in one county a general midwifery fee of £1 1*s.* when in another only half that amount is asked? Certainly, whilst acknowledging that each town must be treated to some extent on its own merits, nevertheless this action of the Lincoln practitioners prejudges the question and tends to show that in this "Battle of the Clubs" there should be some central union or authority to fix what the minimum midwifery fee ought to be. It is, of course, pleasing to think that there is "unanimity" at Lincoln, but surely even that may be bought at too high a price or rather, as in this case, at too low a figure. It would be interesting to know what the midwifery fees in contract practice are in that town at the present time. Apparently they must be 7*s.* 6*d.*, with 2*s.* 6*d.* extra for "putting on the forceps." It is, however, too serious a question to joke about, and I hope due attention will be called to the matter and the Lincoln practitioners urged to rearrange this obnoxious rule No. 5 about midwifery and demand a minimum uniform fee of one guinea, or certainly not less than a 15*s.* fee, and for all primiparæ one guinea.

Charging an extra fee (4*s.* 6*d.*) for "operative midwifery," by which term I conclude that "putting on the forceps" is generally implied—certainly the general public do not consider anything an "operation" unless "instruments" are used—I look upon as an inadequate and vexatious addendum. It is certainly likely in many instances to lead to unpleasantness with one's patients, as we shall be sure to get the credit, albeit, I hope, undeservedly, of "using instruments" to obtain the extra nine sixpences. For obvious reasons I do not sign my name, but

Remain, Sirs, yours faithfully,

April 4th, 1896. A MIDLAND MEDICAL MAN.

*** Our correspondent's letter reveals a difficulty which all have known to be present in this matter. It is difficult enough to obtain unanimity of opinion in one district, but for the present at least it must be impossible to obtain unanimity among a number of districts. Any attempt at over-centralisation as a definite tariff of fees to be maintained universally throughout the United Kingdom would probably end in failure. Special reasons will dictate special fees in different districts, and we do not think much practical harm will arise from the fact, which, after all, is a necessity and has to be faced. If the medical men in a given district are unanimous in demanding a fair rate of emolument they will obtain it. The fact that in a neighbouring district united medical opinion has decided in favour of lower emolument may certainly furnish a handle to some of the clubs for grumbling, but it cannot materially affect the position of the medical men of the place.—ED. L.

A HARD CASE.

To the Editors of THE LANCET.

SIRS,—Unless something is done by the medical authorities to abate the evils menacing the profession through the invasion of our rights by the medical sweating commercial companies, great distress and trouble will be the lot of those practitioners who continue to refuse to degrade their calling by accepting the undignified position of medical attendant to the company's assurance members. About ten years ago a practitioner in the south of London—we may call him A.—enjoying a fair amount of practice received a visit from a representative of the company and was requested to allow his name to be added to a list of those who were willing to become the paid servants of the company. Upon A. declining he was informed that he had better reconsider his determination, as there would be no difficulty in securing a medical man in the neighbourhood to accept the post, and inasmuch as the company intended to canvass the district thoroughly it was a certainty that many persons would be induced to join the medical club, and the man who would be appointed would secure a large proportion of the patients of those practitioners who refused to coöperate with the company's agents. Time proved that the company's representative was a truthful prophet. A practitioner (call him B.) residing a few yards from A. accepted the position, and a transfer of several patients from A. to B. was the result of the energetic canvass of the agents. As years have gone on the company have induced so many medical men practising close to A. to accept appointments that now poor A. is to all intents and purposes at the present moment a ruined man. His earnings have so cruelly decreased that pinching poverty has been his lot for a considerable time. His position is now most deplorable. His wife and family have scarcely a change of clothing, and to supply them with proper food and education is becoming more and more a difficulty. He is in daily dread of being sold up by his landlord, who worries him for his rent directly quarter-day arrives. Can you be surprised that he is now beginning to reflect that he has been to blame in permitting his family to suffer in consequence of his refusing to do that which he considered detrimental to the honour of his profession? Why, Sirs, should the medical authorities any longer allow men to do under cover of the protecting wing of a company that they would not dare to do in their individual capacity as private medical practitioners—viz., tout, tout, tout, to get hold of their neighbours' patients and their neighbours' living?

I am, Sirs, yours faithfully,

GENERAL PRACTITIONER.

*** The case is not a unique one. But it is our belief that a time of emancipation is approaching.—ED. L.

THE PEOPLE'S DISPENSARY, LEICESTER.

To the Editors of THE LANCET.

SIRS,—I am prepared to fight in the "Battle of the Clubs" as long as there is a bottle left to rally round, but I think that the People's Dispensary (Leicester) which is criticised by your Commissioner somewhat contemptuously has some claim to survive the general wreck—if wreckage be the order of the day—and for the following two reasons amongst others. Firstly, it is the wish and intention of the board of management to make the pay of the medical staff adequate, but it is handicapped by the competition of the wealthier "provident dispensary." Secondly, cases of abuse of the institution by persons able to pay for medical attendance at ordinary rates have only to be pointed out to the board to be remedied: this is my personal experience, for I have repeatedly refused to attend ineligible members as dispensary patients, and my action has always been upheld by the board. I am altogether opposed to the club and dispensary system, but I think common honesty demands that the fairness of the board of the People's Dispensary should be thus acknowledged.

I am, Sirs, yours faithfully,

Leicester. ALFRED CLARK, L.R.C.P. Edin.

THE ASHANTI EXPEDITION.

(BY OUR SPECIAL WAR CORRESPONDENT.)

II.[1]

Climate and Soil of the Country traversed by the Expeditionary Force.

THE belt of country stretching from Cape Coast Castle to Kumasi, the line of march which our troops covered, lies between the parallels of 5° 8′ and 6° 45′ north latitude and 1° 15′ to 1° 35′ west longitude, therefore well within the equatorial region of Western Africa. Its climate is essentially tropical and notoriously unhealthy; whilst its unsuitability as a residence for Europeans, or even West Indians, must surely be admitted in view of the fact that a death-roll of 16 and a rate of sickness equal to 50 per cent. have been the results of only some six weeks' stay there by our white and coloured troops employed during the recent campaign. From very careful observations taken every four hours, by night as well as by day, and registered by instruments that could thoroughly be relied on, the solar heat, even during the dry season (whilst the harmattan was blowing), cannot in any way be considered excessive, especially in comparison with what is felt in India or even the Soudan. Only on two occasions during the march up or down was 90° F. reached, and even this degree of heat was only maintained for a few hours in the middle of the day, the thermometer having sunk considerably by nightfall. The extreme registers were taken at the rest camp of Kwissa at 2 P.M. on Jan. 9th and also at Prahsu on Dec. 25th, 1895. Kwissa lies to the north of the Monsi Hill and is considered one of the healthiest spots *en route*. The lowest temperature ever recorded during the expedition was 68° F.; this was registered at 4 A.M. on Jan. 6th at the camp of Akusirem. The mean of all the maximum observations recorded from Dec. 15th, 1895, to Jan. 1st, 1896, gives an average highest temperature of 85° F., and that of the lowest an average of 75° F., and taking the mean betwixt these two an all-round temperature of only some 80° F. is shown—surely an amount of heat that could be endured with impunity by well-seasoned and healthy troops. It is therefore not to the amount or persistence of heat but to some other cause or causes that we must look for an explanation of the development of that calamitous form of sickness which has stricken men down, not only in this, but in every other preceding expedition to the Gold Coast. The difference between the dry and wet bulbs averaged about 3·5°. During the winter and rainy season the mean average temperature is about 80° F., and the difference then between wet and dry bulb is about 2° or 2 50°.

On the Gold Coast there are two distinct seasons: one, the dry, commences generally about the middle or end of October, and terminates at the latter part of February or beginning of March. It embraces a period of sometimes over five months, during which season the rainfall is very limited or in some years conspicuous by its entire absence. Fortunately, however, heavy thunderstorms may, and do, occur during the dry season and are very beneficial when they come. First, the heavy rains which accompany these tempests reduce the temperature 3° or 4° and relieve the oppressiveness of the air considerably. Secondly, the increased momentum given to the air by the incursion of these storms disturbs and scatters malarial germs; and, thirdly, the short, heavy downpour of rain which accompanies these "busters" washes down the land, removes any accumulation of filth, carrying it away by surface-made channels, and thence, by contributory streams, deposits it into the main river. But it does more than this, it cleanses by removing the rotting and decaying material left by the receding water on the banks of the river itself.

During the dry season the harmattan, or north-east wind, is prevalent over the Guinea Coast. Blowing as it does over the Soudan desert, it is dry and very parching in character, and has a distinct reputation for arresting vegetation, but it is supposed to be beneficial in checking malaria and fever; if this be so it is probably by drying the air (usually so humid), and thereby rendering it more respirable than it otherwise would be. Sometimes it comes on in November, and in some years it has not made its appearance till February. During this last Ashanti campaign, however, its influence was only felt (and that too sparingly) for two or three days at the end of December, and to its absence may possibly be attributed much of the sickness that has overtaken so many of our men. During the march from Cape Coast Castle to Kumasi there was an entire absence of any wind.

The wet season commences about March and ends in October. It is frequently ushered in by a heavy downpour of rain—sometimes by a tornado; but it is during May and June that these storms are most severely felt. This is supposed to be the unhealthy season; but the supposition is certainly open to doubt. Many observers consider the wet season as the healthier of the two. Experience has abundantly taught us that accumulation of stagnant water, or even the neighbourhood of rivers, is at all periods more or less unhealthy, and if it be admitted that the malarial morbific agent, whatever it may be, results from the decomposition of animal and vegetable matters, or from exhalations from soils recently under water—then, assuredly, that period of the year when the river is most full or the area of the water at its greatest extent should (theoretically) be the least prejudicial to health. Unquestionably, when a river is low its banks are covered with an accumulation of animal and vegetable detritus. The Prah was so at the time of our stay, and was evidently in a fair condition to evolve miasmatic gases into the surrounding atmosphere, while the low-lying lands surrounding Prahsu, always under water during the wet season, were by reason of the dry one converted into black, stinking bogs, and became at once elements for the production of pestilential effluvia. As temperature increases so the water recedes. From day to day a greater surface of muddy soil becomes exposed, and more organic matter is acted upon by the sun and more poisonous gases are abundantly evolved. Many practical men with whom I have conversed upon the subject say that a trading experience of many years has taught them that more sickness occurs in the dry than in the wet season, especially if the harmattan blows intermittently and without its full strength; but all admit the relief and benefit produced by the occurrence of tornadoes. Without their occasional visits life would be unendurable on the western coast of Africa. They usually commence in April and are most violent during the months of May and June. Some are more destructive than others and do a considerable amount of damage by demolishing native buildings, uprooting large trees, and destroying the young growing plantain and banana plants. However, they give ample warning of their approach. Sky signs are never wanting, and if proper precautions are taken by the natives to stay their huts with cane lanyards much destruction of property can be prevented. Some time before the storm bursts a black ring appears above the horizon, and the whole arch of heaven, previously so blue and clear, becomes gradually enveloped in darkness; then a few drops of rain will fall and a light cooling breeze will but ruffle the foliage of the trees, causing their dry leaves to fall and fly about in every direction; then the rumble of distant thunder is heard, sounding louder and louder, and the lightning is seen, becoming brighter and brighter as the tornado approaches. Forked flashes are now incessant, with deafening thunder pealing overhead; the wind has by this time increased to hurricane violence, and the rain comes down in torrents. What makes most impression on a beholder during such a fearful war of the elements is certainly the frequent transition from pitchy darkness to broad glaring light. At one moment nothing is visible, and in another the whole expanse of nature seems suddenly illumined by the vivid lightning so as to make small objects distinctly perceptible even at a distance. A tornado is truly a grand but at the same time terrible sight. Just a month or so before the wet season ends the rains begin to ease off and the weather becomes hazy. During the middle of the day the sun shines brightly, but in the mornings and evenings the whole country is enveloped in heavy dense fogs. Throughout September these lessen appreciably day after day, and at the beginning of October the dry season once more sets in.

Although it is called the dry season it is very questionable if it is so in reality. True, the rains are over; but heavy fogs have taken their place, excessive moisture being ever present in the air, and one might wait in vain for the

FIG. 1.

A running stream of fairly good water at Biafra Edru. Over this one of the Haussas had been placed as guard to prevent the natives polluting it. The illustration shows how thoroughly the sentry recognised the importance of the duty entrusted to him!

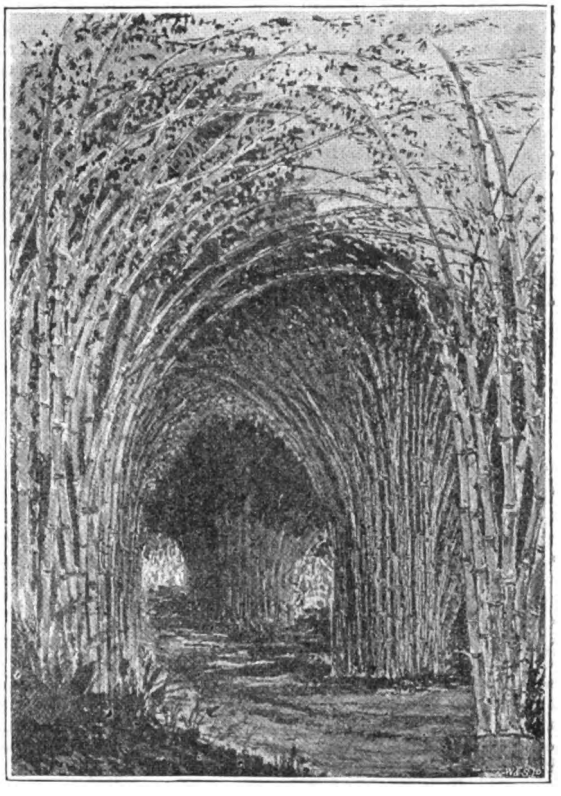
Digitized by Google

advent of one of those bright sunny dry days we are apt to experience in more temperate climes. So loaded is the atmosphere with moisture even during December, January, and February that it is impossible to keep anything free from an investment of green mould unless it be protected by tin, or some other weatherproof substance. Tea done up in the ordinary tinfoil packets becomes caked and unfit for use after a few days' exposure to the air. Salt as soon as opened becomes liquefied, while meat lozenges in paper boxes had a sorry time of it, much to the chagrin of some officers who, relying on the possession of these luxuries and hoping to enjoy a good meal, found on opening the receptacles nothing to reward their confidence but a lump of sodden rotting animal matter at the bottom of the cases. If men took off their clothes at night and hung them quite dry over a camp chair or biscuit box, in the morning they would be found quite wet—not merely damp as our matrons would understand the term, but actually as saturated with water as if they had been rained upon. At Akusirem, that pestilential locality where I and others no doubt received the germs of malarial fever, this excessive humidity was especially noticeable.

In noticing the soil of the Guinea Coast one can well understand the difficulty experienced by an amateur geologist, attached to an expedition moving hurriedly over the country, in obtaining reliable information regarding the geological formation of the various districts through which he has so quickly passed. His field of observation is narrowed to a degree. A long, nearly straight road, bounded on both sides by a dense impenetrable bush, must necessarily offer but poor prospects to the observer, however earnest he may be in searching after truth. Commencing at Cape Coast, the rock upon which the Castle is built is granite, the outcrop rising some eight or nine feet from the sand surrounding it. The native town at its back by a gradual rise seemed built on sand and gneiss, in which some beautiful specimens of opalescent felspar could be observed. Gold (alluvial) in small grains has occasionally been washed out from the mud of the rivulets in the streets after a severe storm of rain; but no remunerative finds have as yet been unearthed at Cape Coast Castle or in its vicinity. About five miles out in a north-north-east direction there is a hill of gneiss through which veins of granite cut. At Akroful, the first rest camp, there was much sand with mica, with lime stone outcrop, and at this place, and this place only, was the water found to contain lime in anything like appreciable quantity. During our trip up to Ashantiland I repeatedly tried to obtain an indication of its presence in the water, but failed on every examination to do so.

Proceeding onwards towards Dunkwa we passed over patches of sand covered here and there with a thin layer of vegetable soil, but as the township above mentioned was approached the sand gave place to a rich chocolate-coloured loam some five or six feet deep, and banks of this rich alluvial deposit flanked the road on either side. One could readily imagine how easily crops of cocoa and spices might be grown on such a soil if anything like care and industry were exhibited in their cultivation. Indeed, cocoa, coffee, bananas, and oranges seemed to be growing wild amidst the tangled undergrowth at this spot. After quitting Dunkwa the soil appeared much the same till the bamboo swamps near Mansu were reached, when we once more came upon the sand with occasional patches of black soil—leafy mould, in fact, the result of decayed vegetation. Mansu is situated upon a slight rise, and here gneiss was once more much in evidence: micaceous slabs three or four inches across could be picked up all over the place. In the river bed there were large quartz boulders and sandstone, but although carefully searched for no gold could be found. Of mica there was an abundance, and a few nodules of water-worn magnetic ironstone were also observed. After quitting Mansu and passing through some grand bamboo swamps (vide Fig. 2) where an alluvial dark-coloured muddy deposit of some four feet in thickness rested on a gneiss bottom, we came by a gradual ascent to Baracou. Here one observed once more the rich chocolate-coloured soil, where in the native gardens, better and more carefully cultivated than heretofore, cocoa, coffee, bananas, and plantain plants were to be seen growing to great perfection. In a hollow some half mile from the native village there was a small stream the bed of which was sand and gneiss; also small blocks of quartz could be seen, but no trace of gold was visible anywhere. By a gradual descent we arrived at Prahsu, the midway resting camp betwixt Cape Coast Castle and Kumasi. The soil here was gneiss, the river coursing from east to west over a sandy bottom with large boulders of sandstone. Beyond the Prah the ground gradually rose to the next resting camp, Tobiassi, where granitic outcrops appeared with highly ferruginous sandstone and hypersthene, which has often been mistaken for granite. Shortly after leaving Tobiassi a long belt of gneiss was fallen in with till nearing Biafra Edru, another military station. Here was a fine flowing stream coursing from west to east over micaceous detritus, with large sandstone rocks nearly horizontally stratified, together with a considerable quantity of ferruginous sand. As customary, we had placed a Haussa guard to look after the non-pollution of the water by the natives. The day was warm. He placed his cap on a tree and went to sleep in the manner represented in the sketch attached (vide Fig. 1). Within a mile

FIG. 2.



This illustration represents one of the very many gigantic bamboo swamps in the neighbourhood of Mansu, through which our troops passed on their way to Kumasi: dark, boggy, mephitic spots of earth which the sun's rays have ceased to illumine for centuries past.

of this place the base of Monsi Hill was reached, where there was found a rich vegetable mould with huge blocks of granite scattered about. Near its summit there were outcrops of quartz with large quantities of disintegrated iron ore, the quartz being extensively traversed by bands of this substance, whilst nodules of magnetic iron ore, from the size of an orange to that of a pea, with smooth, worn surfaces, were observed lying about in every direction. On the northern side of the hill a similar sort of soil occurred, with the exception that quartz was more abundant and the ironstone was less in evidence as the foot of the hill was reached. Midway down the hill I camped, and a few yards off the roadway came upon a waterfall with bright, pure, drinkable water. When we reached Kwissa, situated as it is on an elevated, healthy spot, the soil formation was essentially gneiss, with extensive patches of a dark brown (not red) vegetable mould around. Here large quantities of paw-paw, banana, plantain, and chilli plants are grown, while

Digitized by Google

several cocoa plants and not a few coffee shrubs seemed to have been ruthlessly torn up by the irregular troops who had preceded us in the march. The magnificent baobab (monkey bread—Adansonia digitata) grows to perfection close by the river near this place. There were also to be seen the castor-oil and wild cotton plants. The shea butter tree abounds in the district, but no use seemed to be made of it by the natives. The tall gramineæ and cyperaceæ as well as convolvuli and leguminosæ were everywhere luxuriantly growing on the banks of the stream. There was ageneral haze over the land every morning which disappeared as the sun rose; but the humidity of the air was not nearly so great as we experienced on the other side of the Monsi Hill, and the site evidently had been well chosen for the formation of a rest camp.

On leaving Kwissa, and proceeding northward towards Kumasi, the soil was a ferruginous sand formed by the decomposition of rock with a vegetable mould. The magnificent bombax, with its enormous trunk and widespreading branches, towered aloft in the midst of cassiæ, convolvuli, and other shrubs and trees with their endless variety of tint and shade, and the forest on our flanks seemed denser and more impenetrable than ever. The increased cultivation of yams, bananas, and plantains indicated more extensive habitation than we had yet seen since leaving the Prah district. These gardens of course existed only where the thick bush had in places been cleared away. As we journeyed onward the number of streamlets increased, while the running water was found to be much purer and more usable the nearer we approached our destination in Ashantiland. Considering the climate it has been a grand piece of engineering to cut through and lay our telegraph wire along this forest from Cape Coast Castle to Kumasi, a distance of more than 150 miles, and no small amount of credit must be given to Major Sinclair, R.E., his officers and men, for performing such a masterly piece of work in so expeditious and successful a manner.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Dissection in Board Schools.

THE dissection of rabbits by girls in one of the Board schools seems destined to bring notoriety upon the school in question and upon the system in particular. Whether physiology should be taught in such schools and if a proper knowledge of it can be acquired without practical demonstrations are propositions which give rise to keen discussion. From a science standpoint it is not easy to see what harm can be done to pupils by such an innocent mode of teaching. To skin and prepare a rabbit for cooking is not considered among women to be offensive to good taste; the handling is certainly practical in this instance. Probably if this branch of domestic economy were taught in the schools the permanent benefit to the community would be greater and not call for criticism. Such is the opinion of many outsiders at the present crisis.

Hospital Saturday Fund.

The annual meeting of those interested in this movement was lately held under the presidency of the mayor. The Executive Committee report that the twenty-second collection made in 1895 amounted to £13,057 14*s.* 11*d.*, and the balance brought forward from the previous year was £439 9*s.* 6*d.* The amount of all expenses connected with the collection was 3·89 per cent. per annum. For the seventeenth year there had been an increase in the collections, a gratifying fact to record. The average length of stay of the patients in the home at Tyn-y-Coed was 16 85 days. The cost of maintenance per individual per day was 1*s.* 5·25*d.*; the total cost, including all expenses of administration and wages, was 16*s.* 7·78*d.* per visitor per week. Mr. Smedley, honorary secretary, made some stringent remarks as to the classes from which the contributions come. He said that in 1867 the working classes of Birmingham contributed £567 in all to the medical charities. In 1895 they contributed £25,000; at the same time the subscriptions of the wealthy classes were less in 1895 than in 1867, notwithstanding the increase in the wealth of the town. He pointed out that the hospital did not exist solely for the benefit of the working classes and instanced the value in training for the physicians and surgeons of the future, together with some interesting observations upon the duty of the rich in such matters.

Schools and Swimming.

A discussion upon this subject brings into prominence the value of this branch of physical training, the small percentage of those who learn, and the difficulties attending the facilities for teaching this art. The Athletic Institute has endeavoured to foster the practice by the promotion of contests and prizes. Swimming clubs, and more particularly the City Baths Committee, have been urged to afford opportunities, and now that attention is called to the subject there is a probability of its becoming more general in the elementary schools. Most people will admit the utility and importance of acquiring this knowledge, which has hitherto been sadly neglected. Out of 30,000 school boys in the town, about six in 1000 only are taught at the present time, a fact which speaks for itself.

April 6th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Mersey and Irwell Committee.

AT the meeting of this committee, held in Manchester on the 28th ult., Sir Henry Roscoe was reappointed chemical adviser for twelve months. At the same meeting a report, prepared by the chief inspector, Mr. R. A. Tatton, on the work which has been done for the prevention of river pollution in the Mersey and Irwell watershed since the joint committee was constituted in October, 1891, was received and adopted. The district overseen by the committee has a ratable value of £9,731,007 and contains a population of 2,191,319, so that the work of purifying the rivers is no light one. The inhabitants have grown up with the idea that water-courses and flowing streams were intended by nature to be used as sewers and as the receptacles of all filth and rubbish. The factories disposed of their cinders "either by tipping them direct into the rivers or by depositing them on the banks to be washed away by the first flood." This has been practically stopped, to the great improvement of the beds of the rivers and of the Ship Canal, into which they gradually found their way; for while the dredgings of the canal were formerly composed chiefly of cinders they now contain scarcely any. But few prosecutions have been required to bring about this result, remonstrances being usually sufficient. But it is added significantly, "Constant inspection of the rivers is, however, required." In May, 1892, twenty-seven works were dealing with pollutions under urban authorities, while in March, 1896, forty-seven were in operation, besides five under rural authorities. The works under construction were eight in May, 1892, against thirty in March, 1896. There is the remarkable statement that "the progress made by manufacturers had been greater, as far as results were concerned, than by local authorities," the rivers principally polluted by sewage showing less improvement than those in which manufacturing pollution formed a larger proportion. This illustrates apparently the difficulty usually found in rousing the corporate conscience, the Mersey, with a watershed population of 633,493 and only 60 manufactories, showing little improvement, whereas the Irwell, with a population of 998,625 and 272 manufactories, was decidedly purer, and many of its tributaries which used to be very foul were now in fair order. Partly for this reason and partly because some of their tributaries are polluted from manufactories in Yorkshire and Derbyshire — which means divided authority — the Cheshire rivers show less improvement than those of Lancashire. It is satisfactory to learn that the manufacturers on the whole "had met the committee in a fair spirit, although to many of them the cost of constructing works had been very considerable," and that in comparatively few cases had proceedings been necessary. And this purification is fortunately by no means all loss, for the report adds that "manufacturers who used river water had in many cases, especially on the Medlock and Irwell, already derived considerable benefit." Sir H. Roscoe reported on the sewage affluents analysed during the past month. Of these, six were good, one fair, five unsatisfactory, and two samples, one from Hyde and one from Salford, were bad. As mentioned in a previous letter, Salford has been granted to April 20th to submit an efficient

Digitized by Google

scheme of sewage filtration to the Local Government Board. The effluent sent out from the Manchester sewage works was not spoken of in a manner quite pleasing to Alderman Joseph Thompson, an important member of the Manchester city council and also of the joint committee. It is no doubt difficult, in a case of divided affections, to maintain an evenly-balanced attitude, and therefore not unnatural, perhaps, that at the last meeting of the council he should say that Sir H. Roscoe's report to the joint committee giving the result of his analyses of the effluent from the Manchester sewage works was "misleading." He explained "that as the result of experiments it would be possible to effect a large saving in the estimated cost of the sewage works and get sent out an effluent that would be entirely satisfactory." Manchester is making great efforts to put her house in order so far as drainage is concerned, but a good deal has to be done before perfection will be reached, even if Alderman Thompson's anticipations are realised. It is satisfactory to learn from Sir H. Roscoe that the condition of the water in the Ship Canal is much better than in previous years.

Steaming in Weaving Sheds.

It is a coincidence very interesting to Manchester that the three gentlemen appointed by the Home Secretary to be a committee to inquire into the working of the Cotton Cloth Factories Act, 1889—Sir Henry Roscoe, Sir Wm. Roberts, and Dr. Ransome—should have been so long and closely connected with Manchester and the district. But having been so, they are all the more fully qualified to understand the question of steaming and the introduction of artificial moisture in cotton weaving sheds, and, if found desirable, to suggest amendments in the law.

Report of the Chief Constable.

The report on the work of the Manchester police during the past year is full of interesting if not very agreeable information, and it gives a picture of some phases of life in the city not roseate in hue; but the chairman of the Watch Committee at the last meeting of the City Council considered the report, on the whole, satisfactory. To some extent it is so, as there has been a decrease in several classes of offences. For instance, 217 fewer indictable offences were reported to the police, while 4607 fewer persons were proceeded against for non-indictable offences. The total number arrested during the year was 13,534, and of these 4550 males and 2487 females were drunk when taken into custody. For being drunk and "disorderly" in the streets 5608 persons were arrested and 256 summoned, being a decrease on the previous year of 1124. There is a great difference in the numbers arrested on the different days of the week, Saturday still standing out pre-eminently as the day specially and most conveniently devoted by a large section of the "British working man" class to the business and pleasure of drinking, for among the 5608 arrested 1766 are placed to its credit, while Sunday drops far behind with 804. The numbers then fall to Wednesday, rising a little to Friday, which has, however, only about a third of Saturday's number. There has been a decrease of 1033 on the number arrested for the same cause last year, which is encouraging so far as it goes—which is not very far. Of the chronic drunkards 5 had been in custody respectively 174, 131, 105, 101, and 97 times, so that their recurrent appearances before the court must be an almost continuous grim sort of comedy. For the accommodation of these people and sundry Manchester can boast of 517 public-houses and 2500 "beer and wine houses"—a number more than called for by the reasonable requirements of the people. Happily, they are not likely to be multiplied without careful consideration, and at the Brewster Sessions last August fifteen licences were refused. During the year 608 "juvenile offenders" were arrested—509 boys and 99 girls. Of this number 52 boys and 27 girls were little ones under ten years of age, most of them no doubt following their parents in the pathway of drink and crime. There are 286 registered common lodging houses in Manchester, which are constantly visited by officers appointed for the purpose to see that the regulations of the Common Lodging Houses Act are fully carried out. In addition to their functions in relation to crime the police have others which are almost as valuable to the community. They are of the greatest possible help to the sanitary department of the corporation and act as very efficient sanitary inspectors. In addition to securing some thousands of lost or ownerless dogs, most of which were consigned to a painless death, the police restored 3657 lost children to their homes last year, and they distributed 8047 bottles of medicine to poor people. This last may be thought a questionable proceeding, but presumably it was a simple diarrhœa mixture warranted not to kill.

Opening of the Failsworth Sewage Works.

An important addition to the means for the purification of the sewage of the district has just been made at Failsworth, an outlying suburb of Manchester, where new sewage works were opened on Thursday last. The chairman of the sewage committee of the district council spoke in glowing language and said: "Practical experiments had conclusively proved that the system which they were adopting was the very embodiment of sanitary science and experience brought down to modern times, producing as an effluent water which certainly appeared fit to drink." This looks as if he were too cautious to test it so far. A dinner in the evening at the Belle Vue Gardens followed the inspection of the precipitation tanks and filter beds, which were seen in operation. The cost of the scheme, including land, sewering, and everything complete, was £34,800. The cost of the outfall works was about £8700.

The Chorlton Workhouse Dietary.

Some time ago the Chorlton board of guardians, of which Dr. Rhodes is the chairman, decided to make some improvements in the diet and clothing of the inmates of the workhouse. It was foretold that this would lead to an increased cost of 7*d.* per week per head, but there has been instead a slight decrease. Between Michaelmas 1894 and 1895 "the average weekly cost per head of the in-door poor for provisions, medicine, necessaries, and clothing was 4*s.* 1½*d.*, whereas for 1895 it was only 3*s.* 11½*d.*, or an actual reduction of 1½*d.* per head per week as compared with 1894, when the improved dietary was not in force." There seems to be some doubt of the Local Government Board allowing this improved dietary to be continued, as it interferes with uniformity. In commenting on these matters the chairman said that as to the improved dietary and clothing the return showed that "humanity was sometimes the best policy as well as honesty," and that the reduction of 1½*d.* a head in the weekly cost of maintenance meant a saving of £800 a year. He hoped the ratepayers would remember that, if the Local Government Board persisted in the refusal to sanction the dietary.

Lady Poor-law Guardians.

In the Chorlton Union there are now six ladies on the board, one having been returned the other day for the Chorlton township. She has long taken an intelligent interest in sanitary matters and will be a very useful member of the board. In the Broughton township of the Salford Union, where there were eight candidates, a lady headed the poll with a considerable majority. In one matter the presence of ladies will prove to be economical, for in general they have exercised a moderating influence over the tendencies of male guardians to become members of costly deputations.

April 8th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Glasgow.

THE list of those who are to receive the honorary degree of LL.D. at the graduation ceremony on the 14th inst. includes the names of Dr. Thomas Reid, Lecturer on Ophthalmology in the University; Mr. W. Thistleton Dyer, F.R.S., director of the Royal Botanic Gardens, Kew; and Mr. Jno. Ure, a former Lord Provost of Glasgow and the first chairman of the Public Health Committee, in which capacity he did important work in organising the sanitary system of the city. At the meeting of the general council on the 1st inst. the ordinances recently issued by the Universities Commission were discussed, and it was resolved to petition Parliament against the ordinance dealing with the power of the University Court to readjust the conditions upon which any chair was held at the occurrence of a vacancy; the council was of the opinion that the powers of the Court in this direction ought to be increased. Attention was also drawn to the fact that under the present circumstances the women students in Queen Margaret College were placed at a disadvantage as compared with the male students of the University, in consequence of the lecturers in Queen Margaret College not taking part in the degree examinations. The

Digitized by Google

matter was referred to a committee to report to the next meeting of the council.

Presentations to Medical Men.

Dr. Cluckie, Greenock, upon his retiring from the town council, has been presented by the members of the council with a handsome silver tea-service in recognition of his public services. Dr. Cluckie has been a town councillor and bailie for several years. He is surgeon to the Greenock Eye Infirmary.—The ambulance class of the Govan police have presented Dr. Barras with a microscope as an acknowledgment of the assistance he has rendered to the class as their instructor.

Barony Parish Council, Glasgow.

The report of Dr. Fraser, the Commissioner in Lunacy, who visited the asylum on Feb. 2nd and 3rd, shows that the admission-rate continues to be high, being an average of 32 patients per month. The ratio of recoveries is very satisfactory, having been since the last report 40·3 per cent. and 47·9 per cent. of the men and women respectively admitted. The medical and general care of the patients and the management and order of the institution are noticed as worthy of commendation. A somewhat heated discussion took place at the last meeting of the council upon a proposal to give a donation to the St. Elizabeth Nursing Home, which is under Roman Catholic management. It has been the custom of the council to give a grant to the Glasgow Sick Poor Nursing Association, and it was stated at the meeting that this association refused to employ Roman Catholic nurses, and that therefore the St. Elizabeth Home should also be assisted. It is a matter for regret that a sectarian dispute should arise in connexion with the humane work of giving nursing assistance to the sick poor, but the responsibility may fairly be placed on those who adopt a purely charitable designation but in practice exclude nurses who belong to a particular religious communion.

Galashiels Cottage Hospital.

At the annual meeting on the 31st ult. it was reported that seventy-one patients had been under treatment during the year. The financial statement showed a deficit of £60.

Natural History Society of Glasgow.

At the meeting of this society on the 2nd inst. Dr. Robert Brown, Pollokshields, showed a large number of interesting plants which he had collected in Switzerland. On the same occasion, too, a number of mosses from Simla, collected by Surgeon-Major Shearer, were exhibited.

Glasgow Police Force Medical Officer.

The sub-committee appointed to consider the applications for this appointment having made a short leet sent the following names—viz., Dr. Jno. A. Boyd, Dr. Cumming Grant, and Dr. C. W. Stewart—to the committee. After a vote had been taken—the majority being in favour of Dr. Boyd—it was decided to recommend his name to the council, and he has accordingly been elected. The appointment is worth £350 a year, with an allowance of £50 for travelling expenses.

Aberdeen University Court.

At the last meeting the court appointed Mr. James Hendrick, Lecturer in Agricultural Chemistry in the Glasgow and West of Scotland Technical College, to the new Lectureship on Agricultural Chemistry. Regulations for the Students' Union were approved, and the sale of alcoholic liquors within the University buildings will, under the new rules, be prohibited on all occasions, including dinners or suppers. A legacy of £1000 from the estate of the late Mr. James Jamieson, of Prospect-hill, merchant in Aberdeen, has now become payable, the bequest having been made for the purpose of establishing a lectureship, or towards the endowment of a chair, in the Faculty of Law in the University, as may be determined by the court. It may be mentioned that prominent members of the Students' Union are dissatisfied as to the regulation regarding liquors and as to another rule fixing the opening hour of the billiard-room at 1 P.M. and the closing hour at 10 P.M.

Graduation Ceremony, Aberdeen University.

The graduation ceremony in all the Faculties took place on Saturday for the first time in the Mitchell Hall, Marischal College, in presence of a crowded audience.

Bequests to Aberdeen Hospitals.

Through the death of a life-rentrix the following among other Aberdeen institutions benefit from the estate alluded to above: the Royal Infirmary, £500; the Hospital for Incurables, £250; the Deaf and Dumb Institution, £250; and the Hospital for Sick Children, £250.

Outbreak of Small-pox at Alford, Aberdeenshire.

Towards the end of last week it was found that four cases of small-pox had occurred at Alford, a village about thirty miles from the city of Aberdeen. The county medical officer, Dr. Watt, at once took every precaution to prevent the spread of the disease.

Aboyne Ambulance Class.

On the 2nd inst. in Aboyne (Aberdeenshire) Public Hall the Marchioness of Huntly presented the medals and certificates to the members of the ambulance class which had been conducted by Dr. D. D. Mackintosh. Lord Huntly and Sir W. C. Brooks of Glen Tana both spoke on the importance of ambulance work, and the lecturer was thereafter presented with a handsome dining-room clock.

Outbreak of Small-pox at Alford, Aberdeenshire.

The epidemic has spread from Alford into the Cluny district, where up to Sunday night five cases were reported. Under the directions of the county medical officer energetic action is being taken in the direction of revaccination. The origin of the outbreak has been traced to a child brought by the parents to Alford from South Shields on Feb. 12th.

Dr. W. Findlay of Aberdeen has been appointed by the town council of that city as medical attendant of the employés of the cleansing and lighting departments.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The "Moy-Mell" Entertainment for the Children's Hospital.

THE entertainment in aid of the Children's Hospital, Temple-street, Dublin, will take place on the 7th inst., being Easter Tuesday. The whole of the Rotunda has been engaged and no less a sum than £500 spent on the decorations for the occasion. The *fête* will doubtless be a very great success, for it is under very distinguished and popular patronage, while the city happens to be at present crowded with visitors brought by the excursion trains from all parts of Ireland.

The Athlone Union Hospital.

The guardians of this union were, it will be remembered, dismissed last year by a sealed order of the Local Government Board on account of their refusal to appoint a trained night nurse in the infirmary. The last meeting of the vice-guardians took place on Saturday, the 4th inst., when their turn as managers of the union came to an end. Many improvements have been made and the rates collected in such a satisfactory manner that there is at present a balance of £5251 in favour of the board.

Health of Belfast.

At the meeting of the city council, held on April 1st, the medical superintendent officer of health reported that the health of the city seems gradually improving and contrasts very favourably with that of the corresponding period of last year, more especially in the deaths from diseases of the respiratory organs, which, owing to influenza, were then numerous. Some cases of that disease have occurred latterly, but not sufficient in number or severity to materially affect the death-rate. The epidemic of scarlet fever which seemed to have passed away has returned, and the cases are again numerous though the mortality is light. Measles, which has been prevalent for some months past in the Ballymacarrett district, has now spread to the open parts of the city. The deaths from measles and typhoid fever are few as yet; the death-rate was 25·7 from all causes. At an inquest on April 4th the coroner, in referring to the death-rate of Belfast, said it was the highest in Great Britain with the exception of Galway. In regard to infants he said it was an extraordinary fact that of every 100 persons dying in Belfast every week or month, as the case might be, 25 of them were children under one year of age. One of the main reasons for this was the fact that the parents would not take the trouble of bringing in a medical man, although they could get the services of a medical man in all quarters free of charge.

Digitized by Google

The Belfast Water-supply.

At the present time the total storage in all the reservoirs is some 2,440,492,109 gallons, the largest store of water ever before available, and is upwards of 265 days' supply for the city of Belfast. This very favourable state of affairs is largely due to the careful working of the waste-water meter system, which has been the means of detecting and controlling the underground and other wastes of water within the commissioners' area of supply. The water-supply has been much increased by the very wet weather of March, during which there were only five days on which rain did not fall, and in which the number of inches of rain was 4·99, while the average is only 2·86. There was literally no March dust during the past month.

The Ulster Medical Society: Antitoxin in Diphtheria.

At the usual monthly meeting, held on April 2nd, Dr. Wadsworth gave an interesting *résumé* of a series of cases of diphtheria treated by him successfully with antitoxin. A prolonged discussion followed in which a large number of the members took part, the entire evening being devoted to the consideration of some of the many questions connected with diphtheria.

Election of Direct Representative for Ireland on the General Medical Council.

As the contest for the position of direct representative on the General Medical Council may be fought out again next November between the provincials and the metropolitans, the following statistics, procured from the files of THE LANCET, may prove interesting:—

Year.	Total metropolitan vote.	Total provincial vote.
1886	1642	398
1891	872	516
1896	1321	757

The metropolitan vote has, in fact, fallen off considerably, whilst the provincial vote has been steadily increasing, being at the recent election double what it was in 1886. In 1896 the successful metropolitan candidate beat the provincial by 109 votes.

The Application of the Sixty-five Rule to Queen's College Professors.

Many have been the attempts of the Treasury to convert the Queen's Colleges into mere civil service departments. At first it was intimated that all professors possessed of an income of over £300 a year should retire on attaining the age of sixty-five, or at furthest at seventy. The professors, regarding this as an encroachment on their rights, pointed to the charter of the College and to the fact that the majority of them were appointed "at the will and pleasure of the Queen," which has been always interpreted as meaning for life. A commission was then appointed, with the result that the commissioners recommended that all the professors should be brought under the provisions of the sixty-five rule. If that recommendation were adopted a cruel injustice would be done to the medical profession engaged in private practice, as, no matter how efficient, they would be liable to be turned adrift on attaining the age limit without even the solatium of a pension. Again the College authorities remonstrated. They pointed out that the statutes could not be altered for the purpose except by Act of Parliament, and urged many reasons against the policy of adopting such a course. In the interests of higher education, and especially in the interests of the Cork School of Medicine generally, I am glad to be in a position to state that I have learned on what I consider thoroughly reliable authority that the Lord-Lieutenant, having considered the whole question carefully, has decided that it is not desirable to apply the sixty-five rule, at least in its entirety, to the Queen's College presidents and professors.

National Registration of Plumbers.

The Lord Mayor of Belfast at a public meeting recently held said it seemed to him that the Worshipful Company of Plumbers was serving the best interests of the trade and at the same time protecting the public from imposition by its excellent system of registration. He considered that the system was of the greatest possible benefit to both master and journeymen and was glad to see it become so popular in Belfast.

Uræmic Aphasia.

IT has hitherto been maintained that cerebral manifestations of uræmic poisoning were of a general character, proofs of the limitation of the activity of the toxines to a particular area of the brain being wanting. Dr. Rendu, physician of the Hôpital Necker, had, however, a case recently in his wards that invalidates this contention.[1] A man aged fifty-six was seized suddenly with an apoplectiform attack. When seen on the morrow by Dr. Rendu the man had regained consciousness, but three symptoms remained—viz., aphasia, right brachial monoplegia, and a systolic bruit at the base. The diagnosis of embolus was made. A few days later, however, the patient was seized with intense dyspnœa, lapsing quickly into Cheyne-Stokes respiration; the urine was scanty and albuminous. Phlebotomy was immediately practised, the analysis of the blood revealing the presence of seventy-five centigrammes of urea per litre. It was evidently a case of uræmia. The blood-letting determined an improvement in the condition, the dyspnœa disappeared, and the somnolence gradually diminished, whilst the vocabulary became more extensive. A month later no trace of either aphasia or monoplegia remained. MM. Ménétrier and Guyot stated that similar instances of uræmic aphasia had come under their notice, but that Dr. Rendu's case was peculiar in that paralysis was superadded.

The Sero-therapic Treatment of Acute Alcoholism.

This is the age of experiment, especially in the matter of humoral therapeutics. Had M. Toulouse's communication relative to the above heading not been presented to the grave and scientific Société de Biologie (March 28th) I should hardly have ventured to report it in the columns of THE LANCET. Thinking that poisoning with large doses of alcohol has perhaps the effect of rousing the organism and thus creating a barrier of self-defence by inducing the secretion of products capable of nullifying the action of the alcohol, M. Toulouse administered to two dogs for one week a daily dose of 40 grammes of ethylic alcohol. The serum of those animals was then injected in the course of one day in three separate doses of 8 c.c. into the subcutaneous tissues of a patient suffering from acute alcoholic delirium. The next day the fever is said to have disappeared and lucidity to have returned. M. Toulouse states that he is engaged in further researches calculated to throw light on the specific or non-specific properties of the serum employed. Should the method prove really useful we must expect to see in the near future a British Dogs' Total Abstinence Society in full working order, for faddists will not fail to urge the wickedness of corrupting the morals of the canine race in order to save a mere man from the consequences of his own debased habits.

A Sign of the Times.

I informed your readers in a recent number of the regulations controlling the admission into France of cattle, all of which, excepting such as are intended to be slaughtered within a week, have to be submitted at the frontier to the tuberculin test. That the public is fully alive to the danger of absorbing milk derived from a tuberculous cow is proved by the exhibition in the window of a milk-vendor living in the Rue St. Honoré of a card bearing the following notice:—"*Toutes nos vaches ont subi l'épreuve du vaccin de la tuberculose.*" This is up-to-dateness with a vengeance.

Landry's Paralysis from Streptococcic Infection.

Two cases of Landry's paralysis following influenza having been recently reported in THE LANCET,[2] it may be of interest to record an instance of the same disease due to microbic infection. M. Remlingen[3] reports the case, the patient being a non-commissioned officer who, having contracted malaria in Madagascar, was suddenly seized with paraplegia with subsequent evolution of typical Landry's disease. Death ensued on the eleventh day with bulbar symptoms. The necropsy revealed only slight congestion of the anterior cornua. Cultures made from nerve tissue collected at various points in the cord yielded the streptococcus in a state of purity, the microbe being especially abundant in the cervical

Digitized by Google

region. Inoculation into the rabbit gave a negative result. Sections of the cord treated according to Nissl's method showed the presence of streptococci in the cervical region; they were only found between the large cells of the anterior horns. These cells presented in several places a rupture of their prolongations—a lesion already pointed out in Landry's disease by MM. Marinesco, Ballet, and Dutil. The vessels of the anterior fissure and their ramifications into the anterior horns were in a state of inflammation, and they contained an undue number of white corpuscles. No hæmatozoaires were seen. The streptococcic origin of this case of acute ascending paralysis would thus appear to be distinctly proved, malaria having only had the effect of lessening the resistance of the system to the inroads of the germ.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Berlin Psychiatrical Society.

THE ordinary quarterly meeting of the Berlin Psychiatrical Society took place on March 22nd, Professor H. Laehr, President, being in the chair. Dr. Neisser (Leubus) read a paper on Secondary Mental Weakness in Paranoia, arguing that mental weakness is not necessarily a symptom of paranoia, a view which is in opposition to that held by Professor Hitzig and others. The paper was discussed by Dr. Jastrowitz, Professor Moeli, Dr. Koeppen, and Dr. Falkenberg, and Dr. Neisser briefly replied.

The Emperor and Empress Frederick Hospital for Sick Children.

At the fifth annual meeting of the trustees and supporters of this hospital, held on March 22nd, Professor Virchow, who was in the chair, said that there had been 11,480 patients during last year; 8831 new cases were treated in the out-patient department, and 2049 in-patients were admitted, showing increases of 1711 and 300 respectively as compared with the previous year. The death-rate was lower by 26 per cent. than the corresponding one of the previous twelve months, and there is no doubt as to this good result being chiefly brought about by the efficacious antitoxin treatment of diphtheria. On the other hand, the treatment of scarlet fever with Dr. Marmoreck's anti-streptococcic serum has been rather discouraging, 25 per cent. of the cases proving fatal. The wards of the infirmary have been so crowded of late as to necessitate the building of an additional pavilion. The income from all sources during the year was 158,492 marks, and the total expenditure was 158,149 marks.

Congress of the South German Laryngologists.

The Third Congress of the South German Laryngologists will be held on Whit-Monday, May 25th, at Heidelberg.

A Female Assistant Medical Officer to a Lunatic Asylum.

Miss Sieglinde Stier, M.D., has been appointed assistant medical officer at Dr. Leehr's private asylum at Zehlendorf, near Berlin. Miss Stier has hitherto held the office of assistant medical officer to the infirmary at Dessau.

Professor Virchow.

At the last meeting of the Berlin Medical Society Professor Virchow was unanimously elected representative of the society at the twenty-fifth annual Congress of the German Surgical Society.

April 6th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Wounded at Naples.

THE Neapolitan Ospedale della Trinità now accommodates 111 of the wounded brought from the field of Abba Carima and landed at Naples from the *Sumatra*. The gratitude of the poor fellows at finding themselves in comfortable beds and properly cared for may be understood when many of them declare that for three months from their departure for the seat of war till their return the other day fresh, pure water had not touched their skins. The medical staff have many difficulties to overcome, aggravated by the conditions under which the wounded were transported from Massowah and by the importunities of relatives, friends, and the outside world generally to see the patients and hear what they have to tell. Owing to the system of communication which has kept Italy in the dark as to the fate of her sons in Abyssinia, the Neapolitan and other hospitals are literally besieged by fathers, mothers, sisters, and brothers clamorous for news of their near and dear ones. Up to the point at which the admission of these outsiders would prejudice treatment and recovery the medical staff have thrown no unnecessary obstacles in the way of interviews between the wounded and their relatives, and the scenes of which they have been witnesses are described to me as touching in the extreme. One detail the soldiers under treatment are unanimous upon and it is this—the savage cruelty of their antagonists. An Italian officer "crivellato di palle" (riddled with bullets) was breathing his last on the ground when eight Shoans pounced on him and disembowelled him with their spears! Another point on which equal unanimity prevails is the heroism of the army medical staff. Out of twenty surgeons on the battlefield of Abba Carima seventeen were killed in action. Take, for example, Dr. Giuseppe Lombi, who, surprised before he could regain his ambulance, had to fight like a combatant and join in a charge against the advancing hordes. He was among the foremost of the company, who were making head against their assailants when he was wounded in the throat just at the moment he was shouting "Viva l'Italia!" He refused all succour from the soldiers who wanted to carry him out of action and died soon after with his country's name on his lips. Experiences and anecdotes similar to the above are related by the sick and wounded, 227 in number, just landed from the *Bormida*. The Shoan atrocities perpetrated on the fallen are confirmed. As in the case of those disembarked from the *Sumatra*, the wounded brought by the *Bormida* are unanimous in praise of General Arimondi, to whose brigade nearly all belonged. His coolness and courage, they say, would have given the battle a quite different result had he been in command. No authentic news of him is as yet forthcoming, but his soldiers absolutely exclude the report that he died by his own hand.

Death of Professor Mariano Semmola.

As I send off this letter I receive the announcement of the death of one of Italy's most illustrious physicians, a consultant, indeed, of European reputation, whose contributions to THE LANCET are fresh in the recollection of your readers. Dr. Mariano Semmola, Professor of Clinical Medicine in the Neapolitan School, died yesterday of cerebral apoplexy. Next week I shall give some account of his life and work.

April 6th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Hospital for Inebriates at Washington.

A BILL has passed Congress to establish and maintain a hospital for the treatment and cure of persons suffering from the habitual excessive use of alcoholic liquors, opium, and cocaine. The hospital will have the care of persons of the following classes to the extent of its capacity to receive and treat them:—Firstly, such persons as may be committed to the said hospital by the police court or criminal court of the district; and the judges of the said courts shall have power to commit to the said hospital for a period not to exceed ninety days any person who may be convicted of the habitual excessive use of alcoholic liquors who might otherwise be amenable to commitment to the workhouse, and any person so committed may be at any time discharged from such hospital upon proof that he has been cured, and the certificate of the medical superintendent of the said hospital may be accepted as evidence in such proceedings; secondly, such persons as may be recommended for treatment in the said hospital by the commissioners of the district of Columbia.

Bovine Tuberculosis.

The New York State Board represents that a somewhat careful calculation shows that to destroy all the cattle affected with this disease in the State to-day would involve an expenditure of nearly 1,000,000 dollars. Should the eradication of the disease from all herds be once accomplished such rules and regulations as the board is competent

Digitized by Google

to make and enforce would prevent any importation of infected animals from other States and thus permanently protect the people from this great menace to the public health. The great importance of this work may be fully realised when it is stated that of the deaths occurring in this State during the year over 10 per cent. of the entire number from all causes were from pulmonary tuberculosis.

Against Indiscriminate Spitting.

The New York Board of Health has adopted resolutions framed by Dr. Prudden and Dr. Biggs, bacteriologists, regulating expectoration in public conveyances and in public buildings. The new law requires that notices be posted in all public places warning persons against expectorating on the floors. Municipal authorities and surface and elevated railway companies will be required to provide proper receptacles for expectoration and they must be kept thoroughly clean. The resolutions prohibit the common use of knives, forks, and spoons on free-lunch counters in saloons and also the use of roller towels in the lavatories of saloons and restaurants and other public places. Towels in common use at saloon bars are also prohibited.

Tenement House Reform.

The Tenement House Commission has presented to the Legislature a Bill giving the city of New York power to condemn all rear tenements and convert their sites, together with the unoccupied area in front and rear, into courts bounded on all sides by the rear walls only of the existing front buildings. The city is to be authorised to expend 5,000,000 dollars a year in land damages and expenses until the improvement is completed, and the title to the property is to be taken by the city.

Classification of Diseases.

The Surgeon-General believes the classification of diseases and injuries based on that of the Royal College of Physicians of London to be inconsistent in many respects with our present knowledge of the causation and processes of disease. He has therefore constructed a new system in which the causes of disability are aggregated into five principal classes: (1) infectious diseases, general and local; (2) diseases of nutrition, general; (3) structural and functional diseases of organs; (4) accidents and injuries; and (5) unclassified. Many of the diseases now classed as diseases of particular organs are placed among the infectious diseases, such as tonsillitis, pericarditis, and endocarditis. Of the diarrhœal diseases of the old list acute dysentery has been placed among the infectious.

Health of the Army.

The mean strength of the Army of the United States during the year 1895, according to its medical reports, was: Whites, 22,904; Negroes, 2086; Indians, 386; total, 25,376. The admission-rate of the negro troops was considerably less than that of the white soldiers—811·60 as compared with 1116·44 per 1000; and this lower rate was due to a relative freedom from disease, for their admission-rate for injury was as high as that of the white troops. Their number constantly sick was 25·93 per 1000, while the corresponding rate among the whites was 35·18; and the average numbers of days lost by each on account of sickness or injury were, respectively, 9·5 and 12·8. The rate for discharges also was lower among the negroes—9·40 as compared with 13·56 among the white troops. There was little difference in the death-rates of the two races.

Treatment of Drunkenness in the Army.

Surgeon Arthur has reduced the statistics of alcoholism at Vancouver Barracks by treating drunkenness as acute poisoning. He states that the number of cases of simple acute alcoholism that appeared at sick call and during the day when he first assumed charge of the hospital was unusually large and resulted in the laying down of certain rules as an effort to discourage drunkenness as far as it was in his power. No man is taken on the sick report or excused from any duty unless his condition would make it actually dangerous for him to keep at work. A man reported at the hospital in any stage of alcoholism is treated as a case of alcoholic poisoning, taken immediately to the operating room, and his stomach emptied by the use of the stomach pump and thoroughly washed out with a warm 2 per cent. soda solution. After this he is given a bowl of hot beef extract with cayenne pepper and allowed an hour's rest, when he is generally able, however unwilling, to do his duty. If the weather is severe, either hot or cold, it might not be safe in his depressed condition to force a man to work out-of-doors immediately after this procedure, but at that post the extremes are not great and it has in no case resulted prejudicially to the patient. The effect of this treatment has been uniformly excellent. The stomach, emptied of its irritating contents and cleansed of the thick tenacious mucus that is always present in such cases, is much less irritable and rarely rejects the beef extract which is given immediately. The nervous symptoms improve at once, and sedatives administered by the mouth have a far more lasting effect, and in almost all cases the craving for liquor is diminished. In the past ten months only one case has been admitted.

New York, March 28th.

Obituary.

ROBERT MAIN HORNE, M.D. EDIN.

THE death on the 31st ult. of Dr. R. M. Horne, Senior Demonstrator of Physiology in the Owens College, Manchester, has come as a severe blow to his friends. Unwell for nearly a month, a loyal devotion to duty prevented him from taking much-needed rest till a week before his death, when he was found to be suffering from pleurisy. He appeared to be progressing towards convalescence till the morning of the 31st ult., when grave symptoms suddenly supervened and a fatal termination rapidly ensued. Born twenty-seven years ago, after finishing his education at the Stirling High School he entered the University of Edinburgh in 1886, where he showed himself pre-eminent amongst the men of his own year. During his curriculum he gained the Grierson Bursary on three occasions, the Vans Dunlop Scholarship for students of the third year, and medals or prizes in nearly all his classes; whilst, on graduating with first-class honours in 1890, he was awarded the Freeland Barbour Fellowship in Anatomy, Physiology, and Pathology. After graduation he acted as resident surgeon in the Royal Infirmary, and the following year went to Strassburg, where he engaged in original research on the thyroid gland, his results, embodied as a thesis, being awarded by the authorities of his *alma mater* the Gunning Victoria Jubilee Prize in Medicine in 1893. Shortly afterwards he was appointed Junior Demonstrator of Physiology in the Owens College, and more recently became Senior Demonstrator. In 1895 he graduated M.D. with honours, the subject of his thesis being "Muscle Plasma and its Coagulation." His "leaf has perished in the green," when only time and health seemed requisite for the fulfilment of those brilliant possibilities which had been forecast by his academic career. Cheerful in disposition, modest and unassuming, thoughtful and self-sacrificing in the interests of others, as well as warm-hearted and constant in his friendships, his early death will be a lasting loss to those who had the privilege of intimate friendship with him; whilst the profession will be much the poorer for the premature removal of a member endowed with such unusual ability and zeal.

WILLIAM WILSON, M.D. GÖTT., F.R.C.P. LOND.

ENGLISH-SPEAKING practitioners in Italy have lost their Dean in this able and accomplished physician and surgeon, who closed an honourable and successful career at Florence on Wednesday, April 1st.

A student at Guy's and St. Thomas's, young Wilson impressed all his teachers by his devotion to work, and in the clinical departments especially by his skill in diagnosis and his judgment in therapeutics. He took the diploma of the Royal College of Surgeons in 1838 and the same year graduated as Doctor in Medicine in the University of Göttingen, where he attracted the favourable notice of the illustrious Langenbeck. In 1844 he became a Member of the Royal College of Physicians, and enhanced his professional, particularly his clinical, proficiency by frequent and prolonged visits to the chief French and Austrian schools. Early in his career he served on the *Dreadnought* under Mr. George Busk, whose high opinion of his abilities and character as a surgeon confirmed the estimate formed of him at Guy's by Mr. Edward Cock. In medicine proper he distinguished himself as one of the physicians attached to the Royal Free Hospital, on leaving which institution to enter on practice

Digitized by Google

abroad he received the most gratifying attestation of the esteem in which he was held by colleagues like Dr. Thomas B. Peacock and Mr. John Gay.

Having some fifty years ago become physician of Legation at Florence he rapidly rose to be the leading consultant in the English-speaking community there, while he was frequently called in consultation by professional colleagues, Italians and British, in other centres of the peninsula, notably Venice and Rome. Some years ago he delegated the chief portion of his practice to his son, Dr. Charles Blair Wilson, and, indeed, had almost retired from active duty when death struck down that exemplary young physician in the touchingly dramatic circumstances recorded in THE LANCET of Dec. 29th, 1894. From this cruel blow Dr. Wilson never entirely recovered, but, true to the medical enthusiasm which made him to the end a constant attendant at the clinique of the S. Maria Nuova, he once more entered into harness as the best solace open to him. The effort, however, was of brief duration, and, though always welcomed by his old *clientèle* and his younger colleagues, the burden of eighty winters, aggravated by the heaviest loss that could have befallen him, soon made itself felt. About a fortnight ago he was attacked with what turned out to be severe appendicitis and perityphlitis, and after a prolonged struggle in which he was ably supported by colleagues—Italian and British—he succumbed on the evening of Wednesday, April 1st, and on the following Friday was interred in presence of many mourners in the Protestant cemetery.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated on Monday, March 30th:—

Anatomy and Physiology.—Thomas Walsh Tetley, Yorkshire College, Leeds; Thomas Higson, Owens College, Manchester; Hubert Harry Hollick, Alfred Ernest Frear Wilkes, Herbert John Orford, Joseph Frederick Harvey, Lionel Edward Orton, Horace Wilberforce Freer, and James Arthur Lilwall Peirce, Mason College, Birmingham; Joseph Reginald Frost and Hugh Mortimer Thomas, University College, Bristol; John Gatzkell Churton and Adam Pearson Hope-Simpson, University College, Liverpool; Peter Herbert Schollberg, Cambridge University; and Cecil Westland Pilcher, Oxford University.

Anatomy only.—Edwin Garrett Bunbury, University College, Bristol; William Stanley Boothman, Owens College, Manchester; Frank Ryalls Eddison, St. Bartholomew's Hospital; and Arthur Bradshaw Passmore, Durham University and Guy's Hospital.

Physiology only.—Ralph Holt, Royal College of Surgeons in Ireland and Mr. Cooke's School of Anatomy and Physiology; Frank Cooper, Mason College, Birmingham; Stanislaus Marcus Dowling, Catholic University, Dublin; John Harris, Sydney and Durham Universities; Percy Bertram Spurgin, St. Mary's Hospital; and Charles Thomas McClure, London Hospital.

Eighteen gentlemen were referred in both subjects, three in anatomy only, and two in physiology only.

Tuesday, March 31st:—

Anatomy and Physiology.—Bertram Wilmore Moss, Herbert Midgley Reeve, Walter Baynard Hope, Ernest Thomas Jensen, and Arthur George Grant Plumley, Guy's Hospital; Harold St. Clair Elliott, Cambridge University; Henry Chadwick Woodcock, St. Mary's Hospital; George Padgett Taxler, Lewis Augustus Walker, and John Moore Collyns, St. Bartholomew's Hospital; Christopher John Mayhew and Cuthbert Allen Sprawson, King's College, London; John Bernard Davey and Alexander John Knowlton, Middlesex Hospital; Hackworth Stuart, University College; Alexander George Henry Anthonisz, University College, London, and Mr. Cooke's School of Anatomy and Physiology; Julian Taplin, Mason College, Birmingham; Alexander Tateosian Abadjian, London Hospital; and John Francis Cunningham, St. Thomas's Hospital.

Anatomy only.—Victor Samuel Alexander Bell, Cambridge University and St. Bartholomew's Hospital; John Stansfield Gayner, St. Bartholomew's Hospital; and Edmund Clapperton Dean, University College, London.

Fourteen gentlemen were referred in both subjects and three in physiology only.

Wednesday, April 1st:—

Anatomy and Physiology.—Thomas Hall Gandy, Sydney Richard Scott, Hugh William Leonard, and Ralph Harry Vincent, St. Bartholomew's Hospital; Arthur Thompson, Cambridge University and St. Bartholomew's Hospital; William Day French, University College, London, and Mr. Cooke's School of Anatomy and Physiology; Sydney James Evans, Guy's Hospital; Walter James Waters, Percy Lake Hope, and Basil Fawcett, St. Thomas's Hospital; William Layard Griffiths, and William Herbert Davis, University College, London; Arthur George Eldred, London Hospital; Frederick Fenn Elwes, Middlesex Hospital; and William Henry Passmore, Charing-cross Hospital.

Physiology.—Bernard Newmarch Molineux, St. Thomas's Hospital.

Twenty gentlemen were referred in both subjects and one in Anatomy only.

Thursday, April 2nd:—

Anatomy and Physiology.—Alfred Dittlof Benedictus Von Rosen and George Darell Maynard, St. Mary's Hospital; John Newton Dyson, Donald John Munro, Thomas Malcolm Walker, Everard Inseal Davis, Alfred Gelsthorpe Osborn, Arthur Ronald McLachlan, Russell Henry Jocelyn Swan, Joseph Taaffe De Coteau, and Frederick Ernest Hutchinson, Guy's Hospital; Hanway Richard Beale, Yoshihiro Takaki, and Arthur Webb Jones, St. Thomas's Hospital; John Michael Abraham Olivey, Cambridge University and St. Thomas's Hospital; Ernest Lewis Lilley, Charing-cross Hospital; Francis Henry Foulds, St. Mungo's College, Glasgow, and Charing-cross Hospital; Cecil Scarlett Frost, St. Bartholomew's Hospital; Walter Robert Dunstan and Alfred Orme, London Hospital; Timothy Howell Davies, Middlesex Hospital and Cooke's School of Anatomy and Physiology; William Alfred Stedwell Lamborn, St. Mungo's College, Glasgow, and Middlesex Hospital; Alfred John Vernon Betts, Westminster Hospital; Arthur James Tayler and Percy Vosper, King's College, London; and Moung Pha Taw, Medical College, Calcutta, Rangoon General Hospital, and King's College, London.

Anatomy only.—Arthur James Bowman Adams, St. Thomas's Hospital and Cooke's School of Anatomy and Physiology.

Physiology only.—Major Byron Oliver, University College, London; Joseph Cater, King's College, London; John Herbert Yearsley, St. Thomas's Hospital; and Arthur Henry MacNeill Mitchell, St. Mary's Hospital.

Eight gentlemen were referred in both subjects, four in anatomy only, and one in physiology only.

Saturday, April 4th—:

Anatomy and Physiology.—Frank Douglas Turner, Robert Macpherson Barron, and Graham Scales Simpson, Guy's Hospital; Ernest Blair Dowsett, King's College, London, and Guy's Hospital; Alfred Ernest Softly, Hubert Calvert, Harold Samuel Libby, and Arthur Bevan, St. Thomas's Hospital; William Howard Unwin and Peter Lewis Daniel, Charing-cross Hospital; Quirino Bonifacio de Freitas, King's College, London; William Ernest George Maltby, and Robert Edmond Heighes Woodforde St. Bartholomew's Hospital; Ernest Alsager Parsons, Mason College, Birmingham, and Westminster Hospital; Lewis Cook, and Edward John Budd Budd, Westminster Hospital; Edward Merry, and Thomas Chetwood, London Hospital; Philip Maynard Heath, University College, London; and Henry St. Arnand Agate and Octavius Robert Ennion, St. Mary's Hospital.

Fourteen gentlemen were referred in both subjects.

Monday, April 6th:—

Anatomy and Physiology.—James Herbert Sanders, Herbert Dean Pollard, and Alfred Frank Tredgold, London Hospital; Hugh Thomas Dyke Acland, James Goff, Henry Hugh Rose Clarke, Thomas Perrin, and Ernest Clarkson Bourdas, St. Thomas's Hospital; William Edward Peck, David Pratt Rockwood, John Edgar Simpson, University College, London; Thomas Walker Stanley Browne, Alec Densham, Juan José Rodd, and Alfred Reid, Guy's Hospital; Charles Dudley Bishop, Charing-cross Hospital; William Halliburton McMullin, Alexander Brown, King's College, London; Walter Seymour Danks, Harold Sebert Thomas, and John Abernethy Willett St. Bartholomew's Hospital; Charles Thomas Baxter, Middlesex Hospital; and Arthur Solomon Morley, St. George's Hospital.

Thirteen gentlemen were referred in both subjects.

Tuesday, April 7th:—

Anatomy and Physiology.—William Thomas Hillier, Middlesex Hospital; James Sherren, London Hospital; and John Frederick Paul and Henry George Drake-Brockman, St. George's Hospital.

Anatomy only.—Charles Augustus Scott, Charing-cross Hospital; Stephen Joseph Welch, London Hospital and Cooke's School of Anatomy and Physiology; William Moore Bell Sparkes, King's College, London; and Thomas Howard Body and George Minter Brown, Guy's Hospital.

Physiology only.—Benjamin Isaac, Guy's Hospital.

One gentleman was referred in both subjects, two in anatomy only, and two in physiology only.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates passed in the undermentioned subjects at the Primary Examination held on March 31st and April 1st and 2nd:—

Anatomy and Physiology.—George Aldridge, London Hospital; Joseph Cater, King's College; John George Glasgow, St. Thomas's Hospital; Thomas Baker Haig, St. Bartholomew's Hospital; James Hughes Harrison, Sheffield; Henry Cadwaladr Jones, St. Mary's Hospital; William Robert Murison, Edinburgh; Frank Rowland, Birmingham; George Edward Henry Sargent, London Hospital; Reginald Storrs, Leonard Edgar Whitaker, Ernest Dixon Wortley, and Thomas Lancelot Wyndham, St. Bartholomew's Hospital.

Anatomy.—Edward Quaid Ambrose, London Hospital; Charles Harold Bennett, Edinburgh; Frederick Edward Bissell, Birmingham; Kristnalal Datta, Paris and Glasgow; Richard Frank Killery, St. Bartholomew's Hospital; Charles Henry Farquharson, St. Mary's Hospital; Alexander Farrington, St. Bartholomew's Hospital; Reginald John de Gale Ferguson, University College Hospital; Percy Tranter Goodman, St. Thomas's Hospital; Stephen Joseph Welch, London Hospital.

Physiology.—Alfred Lewis Bartram, Cambridge University and Westminster Hospital; George Frederick Beacher, Sheffield; Oliver Charles Youell Cartter, Charing-cross Hospital; George William Hennen Edgelow, London Hospital; Herbert Devas Everington, St. Bartholomew's Hospital; William Wood Forbes, Aberdeen; Samuel John Brookfield Fox, Sheffield; John George Gowland, St. George's Hospital; Thomas Edward Holman, Guy's Hospital;

Digitized by Google

Robert Orford Jones, Guy's Hospital; Ernest Ward Lowry, St. Bartholomew's Hospital; Edward Alexander Le Maistre, London Hospital; Cyril Purdon, Belfast; James Herbert Rhodes, St. Bartholomew's Hospital; Charles Golothorp Sugden, Cambridge and Leeds; Harry War Bennett Walling, Guy's Hospital; Harry Whittaker, Cambridge.

ROYAL COLLEGE OF SURGEONS IN IRELAND: SCHOOLS OF SURGERY: Class Prizes (Winter Session 1895–96).—Descriptive Anatomy: Junior, W. J. Trembath, first; J. S. P. Stewart, second. Senior, D. A. Fitzgerald, first; W J. Anglim, second. Practical Anatomy (first year): Miss R. F. Lynn, first; F. G. Fitzgerald, second; (second year) G. W. Little, first; J. J. Huston, second; (third year) W. M. Falkner and D. Hadden (equal), first; P. H. Falkner, second. Physiology: W. Gavin, first; P. S. O., Reilly, second. Practice of Medicine: D. Hadden, first; F. J. Palmer, second. Surgery: F. A. Benson, first; W. H. May, second. Midwifery: S. G. Longworth, first; Miss L. F. S. Strangman, second. Theoretical Chemistry: C. B. Vance and S. L. Worthington (equal), first; J. S. P. Stewart, second. Pathology: F. J. Palmer, first; S. G. Longman, second. Physics: J. S. P. Stewart, first. The schools opened on Tuesday, April 7th, for the three months' courses of operative surgery, practical chemistry, practical pharmacy, public health, and forensic medicine, materia medica, practical histology, biology, and dissections.

FOREIGN UNIVERSITY INTELLIGENCE.—*Breslau:* Dr. J. Pfannenstiel has been promoted to an Extraordinary Professorship of Gynæcology.—*Lausanne:* Dr. L. Secretan has been appointed Extraordinary Professor of Otology and Laryngology.—*Leipzig:* Dr. Fredrich has been recognised as *privat docent* in Throat Diseases.—*Strassburg:* Dr. Forster, Professor of Hygiene in Amsterdam, has been offered a Professorship if he will migrate, but at present it is uncertain if he will do so.—*St. Petersburg (Military Medical Academy):* Dr. S. S. Bolkin has been appointed Professor of Infectious Diseases and Bacteriology; Dr. N. N. Zhukoff has been recognised as *privat-docent* in Mental and Nervous Diseases; also Dr. D. A. Kamenski as *privat-docent* in Pharmacology and the Science of Natural Mineral Waters.—*Vienna:* Dr. Hans von Hebra has been promoted to an Extraordinary Professorship of Dermatology.

FOOTBALL FATALITY.—On the 6th instant, during a match at Nuneaton between the Nuneaton Town Club and the Sutton team, from the Birmingham district, a player sustained injuries from which he died at the Nuneaton Hospital on Wednesday last.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST.—The annual meeting of the governors of the Royal Hospital for Diseases of the Chest, City-road, was held at the hospital on March 13th, the Lord Mayor presiding. The report showed that during 1895 there were 755 in-patients and 23 844 attendances of out-patients. The income for the year, exclusive of legacies, was £6020, and the total ordinary expenditure was about £7500. It had been found necessary to borrow £1000 from the bankers, and in addition there was the sum of about £1200 due to tradespeople.

ROYAL METEOROLOGICAL SOCIETY.—At the ordinary meeting of the society, to be held at 22, Great George-street, Westminster, on Wednesday, the 15th inst., at 7 30 P.M., Mr. William Ellis, F.R.S., will read a paper on the Mean Amount of Cloud on each Day of the Year at the Royal Observatory, Greenwich, on the Average of the Fifty Years, 1841 to 1890; Mr. E. D. Fridlander will discuss Atmospheric Dust Observations from Various Parts of the World; and Major H. E. Rawson, R.E., will give an Analysis of the Greenwich Rainfall Records from 1879 to 1890, with Special Reference to the Declination of the Sun and Moon.

A MEETING of the Incorporated Society of Medical Officers of Health was held at 197, High Holborn on March 19th, when the secretary submitted the report of the council. In this report the council state that having had their attention called to the action of the Farnborough urban district council in advertising for tenders for the post of medical officer of health, they recommended that the society should in the interests of public health record its strong disapproval of such methods of filling a professional appointment so closely associated with national interests. The report was adopted, and a resolution registering emphatic disapproval of the action of the Farnborough urban district council was carried.

DR. F. SIDNEY GRAMSHAW, whose name appeared in THE LANCET of April 4th as having obtained the degree of M.D. St. Andrew's, passed the necessary examination in 1895, but was compelled to wait until the recent graduation ceremony for his "capping."

A QUARTERLY general meeting of the Society for the Study of Inebriety was held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., on April 9th. Mr. A. E. T. Longhurst read a paper on the Relation of Alcoholic Stimulants to True Physiological Health and their value in the Treatment of Disease.

MENTALLY DEFECTIVE CHILDREN.—At the last meeting of the London branch of the British Association for Child Study Dr. W. S. Colman gave a short but very interesting account of the various classes into which cases of marked mental defect are usually grouped. He insisted strongly upon the necessity of early detection by parents and teachers of any defects of the sense organs.

A CENTRAL HOSPITAL BOARD FOR LONDON.—A special meeting of the council of the Charity Organisation Society is to be held at the Royal United Service Institution, Whitehall, S.W., on Monday next, April 13th, 1896, at 4.30 P.M., to discuss the subject of a central hospital board for London. The Earl of Stamford (the chairman of the council) will preside. We have dealt with the position in a leading article this week.

PRESENTATION.—On Easter Day, April 5th, Mr. Wilson, the medical superintendent of the Croydon Infirmary, Thornton Heath, was presented with a handsome testimonial in the shape of a gold watch with suitable inscription from the united staff of past and present officers at the infirmary as a small token of their respect and esteem. The presentation was made by Nurse Bell, the oldest resident nurse, and accompanied by a kindly letter of greeting from the contributors.

LONDON TEMPERANCE HOSPITAL.—The annual meeting of the governors of the London Temperance Hospital, Hampstead-road, was held at the hospital on the afternoon of March 19th. The report showed that from the foundation of the hospital in 1873 there had been 11,652 in-patients, with 766 deaths, or only a fraction over 6 per cent. During 1895 there were 1066 in-patients, with 99 deaths, equal to a death-rate of 9 3 per cent., and in the same period there were 5842 new out-patients. The same evening there was another meeting, at which the secretary read a report by Sir B. W. Richardson, stating that his belief in the uselessness of alcohol as a medicine was unabated.

THE DIFFUSION OF SMALL-POX.—The information from Gloucester is not reassuring, the new cases last week being said to have occurred at the maintained rate of 30 per diem. Up to Wednesday of last week, from the previous Friday, there had been 176 fresh attacks, 24 deaths, and only 11 discharges from the hospital. Taking the weeks ended since the second week of February the cases have been 61, 50, 79, 130, 155, 154, and, last week, some 200, making a total in the seven weeks of about 830 persons attacked by small-pox in a population of 40,000 people. Here, then, we find within the space of two months as high a rate as 20 per 1000 of the whole city suffering from a preventable disease. The data to the 26th of March showed that of the 693 cases which had occurred 118 had proved fatal, and that of the 365 hospital-treated cases 90 had proved fatal, no fewer than 74 of these latter having occurred in unvaccinated individuals. Not only so, but there had been but one revaccinated patient received into hospital, and the sufferer had been revaccinated fourteen years ago and caught the infection whilst nursing a private patient. With regard to the hospital cases we learn from Dr. Bond that 158 were of once-vaccinated persons, chiefly adults, and of these 11, or 7 per cent., proved fatal; that 207 were of unvaccinated persons, mostly children, with 70 deaths, or 33·8 per cent. Not a single death in a vaccinated person had occurred in an individual under the age of twenty-four years. The great majority of the unvaccinated children recovering from their attack will be disfigured through life, and some will be blind. Of the vaccinated 2, and of the unvaccinated 179, cases were of children under ten years of age; 42 and 14 respectively under twenty years of age, and 114 and 14 respectively over that age.

Digitized by Google

Some 15,000 to 20,000 vaccinations and revaccinations have been already performed in the city—that is, about one-half of the population have yielded to the evidence of facts without the guardians having taken any positive action. The guardians have appointed assistant vaccination officers to make a house-to-house visitation in the interests of all unprotected children, and their task should, under present circumstances, prove an easy one, for even the opponents of vaccination have in many cases willingly submitted themselves to the operation. It is true that as recently as April 1st (*absit omen*) the anti-vaccinators held a demonstration in the Royal Albert Theatre, Gloucester, but popular feeling is no longer with them, for the trade of the city is feeling terribly the strain of the excommunication of the town. An additional case of small-pox is reported from Camborne. Further cases at Cardiff have been removed to hospital. Two deaths are reported from Newport. A second case has been discovered at Birmingham on a canal boat, the victim, since dead, being an unvaccinated child coming from Gloucester. At Cheltenham the town council have placarded the town with posters showing the arrangements made with a large number of medical men for securing gratuitous vaccination and revaccination; and in the Stroud Union exceptional arrangements have also been made for enabling the populace to be vaccinated at numerous places and during a long range of hours. Another employé of the urban district council at Bridgend has contracted the disease. The occurrence of several cases at Brecknock in the last few days of March led the district council to rent an empty house in the town for the isolation of the patients, but the demonstrations of the mob were such as to lead the mayor to publicly state that a house should be secured for the purpose outside the town and away from dwellings. These repeated declarations of the people in different places against the use of tenements in populated parts for the care of small-pox patients denote the growing tendency of the masses to relegate the disease to rural sites for hospital purposes. Many cases have arisen lately in Aberdeenshire, especially in the neighbourhood of Cluny, the original case having apparently been traced to importation from South Shields. Much free vaccination is being performed in the county in consequence. In Dublin small-pox is not quite extinct, the past month having furnished 7 cases to the hospital.

Parliamentary Intelligence.

CURRENT NOTES.

Coal Mines Regulation.

THE Government have made it known that they will very shortly introduce a Coal Mines Regulation Bill, having as its main object the prevention of accidents and the consequent loss of life.

Petroleum Accidents.

The Select Committee of the House of Commons on the sale, storage, and conveyance of petroleum, and on accidents occurring with paraffin lamps, has appointed as its chairman Mr. Mundella, and has begun the examination of witnesses. It devoted a whole sitting to the examination of Mr. A. Spencer of the Public Control Department of the London County Council, who gave interesting evidence as to the risks run in London both in connexion with lamps and with the storage of petroleum, and who recommended the strengthening of the Petroleum Acts in the general interests of the public.

HOUSE OF COMMONS.

TUESDAY, MARCH 31ST.

Public Health Certificates.

Mr. Knowles, on behalf of Mr. Rentoul, asked whether the Local Government Board had recognised the certificate of the Sanitary Institute as a certificate for a sanitary inspector under the Public Health (London) Act, 1891, Section 108 (2) (*d*); whether any other public health bodies had applied for recognition of their certificates, and, if so, their names; whether such approval had been given, and, if not, the reasons for refusal; and whether the committee appointed by the Local Government Board three years since for drawing up a scheme for establishing one examining board in England for the examination of sanitary inspectors did draw up such a scheme, and, if so, when would effect be given to it.—Mr. T. W. Russell, in reply, said the Local Government Board have approved, until they otherwise direct, of the Sanitary Institute as a body to grant certificates for the purposes of the section referred to in the question. The British Institute of Public Health applied for a similar approval, and the Board had reason to believe that application of a like character would be made by other bodies. The application of the British Institute of Public Health was not complied with, as the Board thought it desirable that a joint board should be formed consisting of representatives of various examinations and grant certificates for the purposes of the section. A committee was appointed in 1894 to draw up a scheme for establishing a joint examination board, and they have framed a scheme accordingly. The scheme adopted contemplates that the examination board should be incorporated under the Companies Act, 1862, and application was accordingly made to the Board of Trade. The Board are communicating with the Board of Trade on the subject.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ANDREWS, H. A., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the Hull Infirmary.

BENNETT, C. J., M.R.C.S., has been appointed Medical Officer of Health by the Dixley and Hayfield Rural District Councils respectively.

BERRY, H. P., M.B. Lond., M.R.C.S., has been reappointed Medical Officer by the Grantham Town Council.

BERRY, WILLIAM, L.R.C.P., L.R.C.S. Edin., F.R.C.S. Irel., M.R.C.S., D.P.H. Glasg., has been appointed Medical Officer of Health by the Hanley Urban District Council.

BLACKMORE, B., L.R.C.P., L.M. Irel., has been reappointed Medical Officer by the Tyldesley District Council.

CHRISTIE, MARGARET M. T., M.B. Lond., has been appointed Junior Medical Officer for the Greenwich Workhouse.

COGHLAN, T., L.R.C.S., L.M. Irel., has been appointed Medical Officer for the Kilmacow Dispensary.

CRINION, L. A. J., M.B., B.Ch. Irel., has been appointed Medical Officer for the Rathmore Dispensary District, vice Coady.

DARROLL, W. B., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer for the Brampton Brian Sanitary District of the Knighton Union.

FISHER, V. H., M.B. Dub., L.R.C.S., L.M.R.C.P. Irel., has been reappointed Medical Officer by the Howden Rural District Council.

GALLOWAY, A. R., M.B., C.M. Aberd., has been appointed for the combined office of Assistant Anæsthetist and Assistant Medical Electrician to the Aberdeen Royal Infirmary.

GIBBS, CHARLES, F.R.C.S., has been appointed Assistant Surgeon to Charing-cross Hospital, vice the late Mr. Archie T. Collum.

GOODFELLOW, J. A., M.B., C.M. Glasg., has been reappointed Medical Officer of Health for Brampton.

HARPER, CHARLES, L.R.C.P. Edin., M.R.C.S., has been reappointed Medical Officer of Health for Bath.

HAWKINS, E., M.D., C.M. Edin., has been appointed Medical Officer of Health, Sunderland.

HOPTON, RALPH, M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Hospital for Women and Children at Leeds.

KEMPE, C. M., M.R.C.S., has been appointed, *pro tem.*, Medical Officer of the Workhouse, Steyning Union, vice T. Fuller, resigned.

LE FANU, H. G. P., L.R.C.P., L.R.C.S. Irel., has been appointed Honorary Medical Officer to the Derbyshire Hospital for Sick Children, vice F. E. Taylor, resigned.

MACKAY, J., M.D. Aberd., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer to the Poorhouse, Logierait.

MEAD, G. B. O., L.R.C.P. Edin., M.R.C.S., has been reappointed Medical Officer by the Newmarket Urban District Council.

MIVART, F. ST. GEORGE, M.D. Louvain, L.R.C.P., F.R.C.S. Edin., M.R.C.S., has been appointed Medical Inspector by the Local Government Board.

MONTGOMERY, R. J., M.A., M.B., T.C.D., F.R.C.S.I., has been appointed Ophthalmic Surgeon to the Drumcondra Hospital (Whitworth), Dublin.

NETTLE, WILLIAM, M.R.C.S., has been reappointed Medical Officer of Health for the Liskeard Rural and Urban Sanitary Districts.

PARSONS, F. J. C., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer by the Bridgwater District Council.

ROBERTS, LLEWELLYN W., M.B. Melb., &c., has been appointed House Surgeon to the Victoria Hospital, Folkestone.

SANKEY, J. IVOR, M.R.C.S., L.R.C.P., L.S.A., has been appointed Medical Officer and Public Vaccinator for the Sixth (Brenchley) District of the Tonbridge Union, vice P. W. Streatfield, resigned.

SHEARER, R. P., M.B., C.M. Glasg., has been appointed Medical Officer of Health for the Gotham Sanitary District of the Basford Union.

SOUTHEY, A. J., M.R.C.S., has been reappointed Medical Officer of Health by the Eton Urban District Council.

WALKER, J. D., M.B., M.S. Aberd., has been appointed Junior Assistant Medical Officer to the Cornwall County Asylum.

WEBBER, W. W., L.R.C.P. Edin., M.R.C.S., has been reappointed Medical Officer of Health by the Crewkerne Urban District Council.

WELLS, S. RUSSELL, M.D., B.Sc. Lond., M.R.C.P., has been appointed Medical Registrar to St. George's Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—Resident Medical Officer. Salary £80 per annum, with board and residence.

WREXHAM INFIRMARY AND DISPENSARY.—House Surgeon. Salary £80 per annum, with furnished rooms, gas, coal, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

CRAMPTON.—On March 31st, at Bond-street, W.C., the wife of T. Hobbs Crampton, L.R.C.P. Irel., L.R.C.S. Irel., of a daughter.

CROPPER.—On April 1st, at Syston House, Boscombe, Bournemouth, the wife of John Cropper, M.A., M.B., B.C. Cantab., of a daughter.

ELLERTON.—On March 31st, at Priory-terrace, Leamington, the wife of J. F. Heise Ellerton, M.D. Brux., of a daughter.

FRASER.—On April 3rd, at Burton-road, Carlton, Nottingham, the wife of Alexander Fraser, M.B., C.M. Edin., of a daughter.

LANGDON-DOWN.—On April 6th, at Harley-street, W., the wife of Reginald L. Langdon-Down, M.B., M.R.C.P., of a daughter.

MACGREGOR.—On March 31st, at Hillside, Clayton West, near Huddersfield, the wife of Duncan Alastair MacGregor, M.B. Univ. Edin., of a son.

MARTIN.—On April 3rd, at Southwick-place, Hyde-park, W., the wife of Henry C. Martin, M.D. Edin., of a son.

SANDFORD-SMITH.—On April 5th, at Eltham, Kent, the wife of H. Sandford-Smith, M.R.C.S., L.S.A., of a daughter.

SKYRME.—On March 27th, at Windsor-place, Cardiff, the wife of Hy. E. Skyrme, M.R.C.S., L.R.C.P. Lond., of a daughter.

MARRIAGES.

DUNCAN—WIGHTMAN.—On March 18th, at St. George's, Hanover-square, Duncan Duncan, M.R.C.S. Eng., of Eccleston-street, S.W., to Caroline Agnes, eldest daughter of the late George Wightman, of Clapham.

FINCHAM—GIBBON.—On April 8th, at St. Mary's, Hornsey-rise, N., Ernest C. Fincham, M.R.C.S. Eng., L.R.C.P. Lond., only son of James Fincham, M. Inst.C.E., of Hobart, Tasmania, to Blanche, youngest daughter of the late Richard Gibbon, of Shanghai.

LLOYD—WISKAR.—On April 7th, at the parish church, St. Pancras, Samuel Lloyd, M.D. St. And., of High-street, St. Giles's, to Emma, widow of the late Walter C. Wiskar, of Whitfield-street, Fitzroy-square.

MACKAY—MCHARDY.—On April 8th, at the Cathedral Church of St. Mary, Edinburgh, by the Right Reverend the Bishop of Edinburgh, assisted by the Reverend Irvine K. Anderson, Rector of Tavy St. Mary, Devon, uncle of the bride, George Mackay, M.D., F.R.C.S.E., eldest son of Deputy-Surgeon-General Geo. Mackay, M.D., to Elise Marjory, younger daughter of Lieutenant-Colonel Alex. Burness McHardy, R.E., one of H.M. Prison Commissioners for Scotland.

DEATHS.

ATTER.—On April 1st, at Lillie-road, West Brompton, London, Henry Herbert Atter, Surgeon, aged 33.

BRYCE.—On March 24th, at sea, on s.s. *Inchanga*, James Bryce, M.D. Aberd., late of Puckeridge, Herts, aged 33 years.

BURFORD.—On April 1st, at Greville-road, Kilburn, N.W., Henry Thomas Buttanshaw Burford, M.R.C.S., aged 90.

GREGG.—On March 31st, at Camberwell, the Right Reverend Thomas Huband Gregg, D.D. and M.D. Dubl., Bishop of Verulam, aged 56 years.

KANE.—On Easter Sunday, at Bishopsteignton, Joseph George Auriol Kane, M.D. Dubl., of Exmouth, aged 30.

SARGENT.—On March 27th, at Nice, Arthur Francis Sargent, Surgeon-Major 3rd Bombay Light Infantry, youngest son of the late Rev. John Paine Sargent, Vicar of Cauldon, Staffordshire, aged 43 years.

SMITH.—On April 1st, at Hammersmith, Wilberforce Smith, M.D. Heidelberg, of Stratford-place, aged 51.

THOMAS.—On March 31st, at Mile End House, Llandovery, David Thomas, M.R.C.S., J.P., in his 82nd year.

THORNE.—On April 7th, at Cannes, Annette Maud, only daughter of William Bezly and Annette Mary Thorne, of 53, Upper Brook-street, London.

WELSH.—On April 7th, at Oakdene, Oak Hill-road, Surbiton, Francis Fawcett Welsh, F.R.C.S., aged 79.

WILSON.—On April 1st, at Piazza Madonna, Florence, William Wilson, M.D. Gottingen, F.R.C.S., in his 82nd year.

WREFORD.—On April 4th, at Osborne-road, Newcastle, John William Ernest, only child of John Wreford, M.R.C.S., L.R.C.P.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.).

TUESDAY (14th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2 30 P.M.), Cancer (2 P.M.).

WEDNESDAY (15th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross, (3 P.M.), St Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).

THURSDAY (16th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Great Northern Central (Gynecological, 2 30 P.M.).

FRIDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1 30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.) Gt. Northern Central (2.30 P.M.).

SATURDAY (18th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (13th).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-square, W.C.).—8 P.M. Papers:—Mr. A. Marmaduke Sheild: A Case of Aneurysm by Anastomosis of the Vessels of the Hard Palate, with Hæmorrhage into the Mouth, treated by Excision of a portion of the Jaw.—Mr. Storer Bennett: Report on a Case of Re-united Fractured Human Tooth, with some remarks on the Healing of Wounds of the Dental Pulp.—Mr. C. Tomes: (1) Description of a very remarkable Formation of Secondary Dentine after Fracture of a Tooth; (2) Further Notes on Amalgams.

SOCIETY OF ARTS.—8 P.M. Professor H. A. Miers: Precious Stones. (Cantor Lecture.)

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Cases:—Dr. E. Cautley: Congenital Distensile Tumour of the Neck.—Dr. de Havilland Hall: (1) Osteitis Deformans; (2) Great Enlargement of Leg; (3) Jaundice (? Hydatid of Liver).—Mr. W. H. Battle: (1) Lateral Spinal Meningocele; (2) The Result of Operation in a Case of Spontaneous Dislocation of the Patella.—Dr. Gilbart Smith: Carcinoma of Larynx.—Mr. Clinton Dent: (1) Hairy Mole of Face; (2) Tumour of Abdominal Wall.—Mr. G. R. Turner: Tumour of Neck.

TUESDAY (14th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Surgeon-Captain M. L. Hughes: Note on the Endemic Fever of the Mediterranean.—Mr. R. Barwell: On Spontaneous Dislocation of the Hip, with some remarks on a Class of Cases often mistaken for Rheumatism.

WEDNESDAY (15th).—LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Adjourned Discussion on Foreign Bodies in the Upper Air and Food Passages, introduced by Mr. Charters Symonds at the February meeting.

ROYAL METEOROLOGICAL SOCIETY (22, Gt. George-st., Westminster).—7.30 P.M. Papers:—Mr. W. Ellis: Mean Amount of Cloud on each day of the year at the Royal Observatory, Greenwich, on the average of the fifty years 1841 to 1890.—Major H. E. Rawson: An Analysis of the Greenwich Rainfall Records from 1879 to 1890, with special reference to the Declination of the Sun and Moon. Mr. E. D. Fridlander will open a Discussion on Atmospheric Dust Observations from various parts of the world.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (Limmer's Hotel, Conduit-street, W.).—8 P.M. Dr. F. Fox (Strathpeffer Spa): The Varieties and Treatment of Articular Gout. Discussion on Necessity of Increased Travelling Facilities to the British Health Resorts.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover-sq., W.).—8 P.M. Meeting.

THURSDAY (16th).—HARVEIAN SOCIETY (Stafford Rooms, Pitshborne-street, Edgware-road, W.).—8 30 P.M. Papers:—Dr. W. Hill: Prognosis in Chronic Non-suppurative Catarrh of the Middle Ear.—Mr. R. Johnson: Some Unusual Cases of Swelling of the Parotid Gland. Mr. Dodgson: A Demonstration of the Process of Photography by means of Roentgen's Rays.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the second half-yearly volume for 1895 was given in the issue of Dec. 28th. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1895 are now ready. Bound in cloth, gilt lettered, price 18*s*.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*.; by post, 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

CARDIAC MURMURS AND FRICTIONS HEARD FROM A DISTANCE.

To the Editors of THE LANCET.

SIRS,—The interesting case reported in THE LANCET of April 4th, of a child with a mitral murmur heard from a distance, is by no means unique, as a reference to Section 780: 3 (1890 Edition) of the "Medical Digest" will prove. Dr. Osler in 1880 described a somewhat similar case, and incidentally alluded to several others that had been reported. In Section 753: 5 (Appendix) some remarkable cases of pericardial frictions heard from a distance will be found recorded.

I am, Sirs, yours truly,

South Hampstead, April 4th, 1896. RICHARD NEALE, M.D. Lond.

"THE POISON OF THE PRIMULA."

To the Editors of THE LANCET.

SIRS,—In connexion with the discussion on this subject it may be of interest to note that the Rhus toxicodendron or poison ivy produces when handled an acute dermatitis the inflammation of which is erysipelatous in character, rapidly spreading from the parts first affected all over the body and involving even the mucous membranes. The first case of this description which I saw was under the care of Professor T. R. Fraser in the Royal Infirmary at Edinburgh. A still more curious circumstance is that certain susceptible people are seized with acute eczema after touching the Japanese fancy boxes now so commonly sold in the shops, the explanation being that these boxes are varnished with a preparation made from a species of sumach.

I am, Sirs, yours truly,

Welbeck-street, W., April 6th, 1896. WILLIAM MURRELL.

To the Editors of THE LANCET.

SIRS,—In reply to your inquiry as to the poisonous qualities of the primula, as far as I know the primula obconica is the only one that is known to have poisonous qualities. It seems only to affect a limited number of the persons who have been in contact with it. It causes swelling of the parts and a glossy redness, with intense burning, itching, and tingling, especially severe after the patient retires to rest. These symptoms often remain for two or three days, and after this the fingers seem to shrivel and desquamate. The irritation is most tiresome and depressing, and if continued long tells seriously upon the general health. The parts affected are, as might be expected, the hands and those parts which come into contact with them, more especially the face. The treatment which I have found of the greatest use is the application of the following lotion—zinci oxidi, ʒ iii.; calaminæ, ʒ iv.; glycerini plumbi subacetatis, ʒ iss.; liquor carbonis picis, ʒi. to ʒ ii.; spiritus, ʒi.; aquæ sambuci ad ʒ viii.—or an ointment of cocaine. A solution of carbolic acid is also said to be very efficacious. As the primula obconica is now very extensively cultivated in greenhouses and seeing that it remains in flower all the year round, its effects ought to be better known to the profession than they have hitherto been, as the following case will show. A woman, fifty-two years of age, was brought under my notice suffering from repeated and severe inflammation and swelling of the fingers and palms of the hands, also occasionally of the eyelids and ears, rendering her nights sleepless from the pain and irritation. This state of affairs had continued for such a length of time that her general health began to suffer and she was becoming melancholy and desponding. She had consulted several medical men who had pronounced the case to be a recurrent urticaria. She had been put under a most rigid diet for more than twelve months, but without any benefit. Local sedatives had relieved the symptoms for an hour or two at a time, but without permanent good. Internal remedies of various kinds were adopted with no better results. But it had always been noticed that when she was away from home she at once improved and for a time entirely lost all the symptoms, but on her return home she began to suffer as badly as ever. Last summer she went away and, as usual, the symptoms disappeared. At the end of about a month her husband sent her a basket of flowers which had been grown in the conservatory at home, and within twenty-four hours the old trouble began. The writer of these notes calling and seeing the primula obconica on the table and knowing its poisonous effects at once solved the problem, and the patient has had no return of the trouble since that time.—I am, Sirs, yours faithfully,

Blackpool, March 31st, 1896. F. W. A. STOTT.

To the Editors of THE LANCET.

SIRS,—In reference to your note on the primula obconica it appears to be without doubt that the plant secretes a virulent poison, and that the primula sinensis also secretes a poison, presumably the same only less virulent, but considering the number of plants in cultivation the percentage of persons susceptible to the poison must be very small. A difficulty in bringing home the charge to the primula is that the effect does not immediately follow the cause, consequently many cases escape recognition. Last winter I had several plants of the obconica, and I suffered from numerous attacks of the eruption until I suspected the cause, and this subsequently I confirmed by handling when my skin was healthy. In about eight hours' time the first symptom appeared—viz., itching between the fingers and on the forehead—and soon an erythematous eruption appeared, which rapidly spread over the whole face, the palms, and up the flexor surfaces of the arms. The rash is slightly raised, but the edges are not well defined. The irritation is intense. Bullæ formed between the fingers and on the forehead. The duration of the attack was three days, the rash disappearing and the irritation gradually abating; desquamation in large flakes followed. I have seen only three cases of poisoning by the primula obconica, but have heard of several others. One of these was a market gardener who potted yearly several scores of this plant, but who never suffered any ill-effect until he handled them with a scratched hand; the rash then appeared on one arm only. A few weeks ago I handled some leaves of the primula sinensis, this was followed by a mild erythematous attack with itching, which, however, only lasted a few hours; and almost the same time I saw a patient with what I diagnosed as "primula erythema." He had been handling the primula sinensis the day before the eruption appeared.

I am, Sirs, yours faithfully,

Andover, April 6th, 1896. J. F. GILLETT, M.B.

THE APPOINTMENT OF MEDICAL OFFICERS OF HEALTH: TWO QUESTIONS.

To the Editors of THE LANCET.

SIRS,—Will you kindly reply through the medium of THE LANCET to the following queries: (*a*) Are the duties of a medical officer of health set out in pamphlet form by the Local Government Board? If so, where can I apply for a cheap copy? (*b*) I am about to take up my residence in a "union district" where there is no resident medical man, and the medical officer for the poor lives in another district and is the holder of three or four such appointments outside his residential district. Now, I am told that on taking up my residence in this district I, being the only resident medical man therein, can "demand" (that is the word my informant used) the post of medical officer for the poor at the hands of the guardians for the district in which I reside, and that it will be given to me in one month after my application. Is this correct? Thanking you in anticipation, I am, Sirs, yours faithfully,

April 4th, 1896. M.O.H.

*** (*a*) Yes; we send our correspondent an "order" to rural sanitary authorities issued by the Local Government Board, and procurable from Messrs. Eyre and Spottiswoode. (*b*) He should apply to the guardians to be appointed when the year of office of the present holder terminates, and should inform this Board he has done so because he is resident in the district. He will probably find the appointment is annual only, on account of non-residence of the present holder. He cannot demand the appointment, but residence in the district is an extremely strong claim in the view of the Local Government Board to the office.—ED. L.

Young Student will find his first question answered as definitely as it can be by a leading article in our issue of Aug. 17th, 1895. He will be right to place M.D. after his name; he should certainly affix also the letters designating the university where he obtained the degree. With regard to his second question, we recommend him to address the secretaries, Dr. Albert Mills, 30, Rue du Pépin, Brussels, or Mr. Walter Reeve, 28, Victoria-street, Westminster.

THE QUESTION OF MEDICAL PRIVILEGE IN MICHIGAN.

A JUDGE has decided at Battle Creek, Michigan, against professional secrets. A physician must testify in regard to the ailments of his patients. Judges must either go further or not so far. They must define the circumstances in which secrets are to be disclosed, otherwise even judges may lose authority with the public.

CLUB MEMBERS AS PRIVATE PATIENTS.

To the Editors of THE LANCET.

SIRS,—Now that club practice is such a burning question I should like your opinion on the following case, which must be only one out of many in the country, though I have never seen the point raised.

A fairly well-to-do tradesman, who is a member of the Order of ———, came to me. He said he knew the payment by the club was too small, and that if I would do my best he would pay me for my attendance. I replied that he need not imagine that he would be better looked after by that arrangement as I tried to do my duty to club and private patients alike, but that I quite agreed that a man in his position ought not to take advantage of the club and that I would accept his offer on that ground. I made the note in my day-book, "Is in the ——— Club, but wishes to pay," and afterwards mentioned the matter to my assistant. At the usual time I sent in my account and was met by the threat to bring the matter before the club for having tried to charge a member for attendance. I consulted some of the officials and found that my patient had been to the lodge, who declined to interfere. They assured me that the club would not take part against me as they regarded the matter as a private affair between us. Now what are my rights? Am I justified in making such an arrangement with a member? If so, can he legally be made to abide by it? Is the note in my day-book of any value as evidence?

I am, Sirs, yours faithfully,

March 23rd, 1896. CLUB DOCTOR.

*** The point raised by our correspondent is very interesting but purely legal. The action of the club is to its credit, and so was the first action of the patient, who doubtless knew that he was not doing right in taking medical service from the club medical officer on club terms. He acted very unworthily of his better moments when he fell back on his club rights and tried to move the club to legal action against the medical officer. We are very doubtful of the legal power of our correspondent to enforce other payment than the club terms require. The patient has the principle of contract on his side. Had he paid cheerfully an honorarium the matter would have been different Nevertheless, the case is very valuable as showing the injustice of the club system.—ED. L.

Mr. Walter J. Bell.—We cannot break through our rule of never giving medical or surgical advice.

Mr. F. M. Beaumont is thanked for his interesting extracts from the *Weekly Entertainer*.

H. G. D.—The question is not simple of answer. We will give it our attention.

"ADVERTISING DENTISTS IN KENSINGTON."

To the Editors of THE LANCET.

SIRS,—I most emphatically deny having any knowledge whatever of the paragraph respecting myself you reproduce in THE LANCET of April 4th from *Society*, and I am in no way responsible for its appearance in that paper. I consider your heading "Advertising Dentists" most offensive and unjust to one who has never in his life advertised dentistry. I am now waiting for the advice of my solicitor as to his view of that question. With regard to your reference to the Irish College of Surgeons, that authority—which, after all, is the only one primarily concerned in this matter—is quite capable of guarding its own interests. I am, Sirs, yours faithfully,

Lancaster-gate, W., April 7th, 1896. W. CADWALADR JONES.

*** The fact remains that Mr. Cadwaladr Jones's dentistry has been advertised. We never said that he was responsible for this. What we did say was that it was difficult to acquit him of all responsibility inasmuch as the offending paragraph that we quoted was not the only one of its sort that had appeared. We are glad to print his disclaimer of all knowledge of the paragraph, and recommend him to ask the editor of *Society* to withhold similar attentions for the future.—ED. L.

LEGAL RECOVERY OF MEDICAL FEES.

A COURT of law in the United States of America has decided in favour of Dr. A. C. Bernays in his action to recover $5000 (£1000) for the trephining of a wealthy lady. The learned judge remarked that the plaintiff gained his case not merely because the defendant's circumstances enabled her to pay so large a fee without serious inconvenience, but also because the operation of itself was well worth the sum charged. Our contemporary, the *American Journal of Surgery and Gynæcology*, in recording the case adds: "Large retainers to lawyers go unquestioned; that is a matter of saving of dollars and cents. But when a surgeon demands a fairly reasonable sum—say, $3000 to $5000—for an operation which saved a life the lawyers and the general public hold up their hands in horror and cry 'Exorbitant!' The precedent created in this case will doubtless lead to the establishment of higher fees than those hitherto sustained in our courts—a consummation devoutly to be wished."

THE NEW PHOTOGRAPHY.

WE have received from the Electric Photo-Printing Co., Short Hill, Nottingham, a book of photographs illustrating a lecture on the new photography delivered at University College, Nottingham, by Professor Heaton, M.A. The photographs, which were taken by Mr. A. H. Simpson, show a living boy's hand (aged ten) after an exposure of two and a half minutes, the hand of a living woman containing a needle, and other illustrations of a like nature. In the photograph of a man's foot, taken with the boot on (exposure ten minutes), the bones and articulations are distinctly seen, and the skeletal framework of a mouse, a rat, and a frog can be traced in other pictures with more or less distinctness. The published price of the book is 1*s.* 6d.

ERRATUM.—By an obvious slip of the pen in our report of the trial of Kitson *v.* Playfair on page 961 of our last issue the name of Dr. Williams (line fifty-seven) was substituted for that of Dr. Playfair in the address of Sir Frank Lockwood to the jury. The first question submitted to the jury should read, "Were the words uttered as alleged?"

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Sheffield Independent, Norfolk Chronicle, Kingston News, Birmingham Post, Devon Gazette, Manchester Guardian, Northern Telegraph, Ayrshire Post, Times of India, Lancashire Express, Blackburn Times, Scarborough Evening News, Worcester Echo, Pioneer Mail, Architect, Eastern Morning News, Journal des Debats (Paris), Western Daily Press, Scotsman, Builder, Dundee Advertiser, Midland Counties Express, Durham Chronicle, Southport Visitor, Bradford Observer, Somerset County Herald, Hereford Times, Keene's Bath Journal, Yorkshire Post, Bristol Mercury, Leicester Post, Glasgow Herald, Irish Times, The Speaker, Newcastle Journal, Rochester Journal, Grays Standard, Cambridge Express, Bedfordshire Standard, Liverpool Daily Post, Leeds Mercury, Carnarvon Herald, City Press, Putney News, Newport Pagnell Gazette, Sporting Times, Sevenoaks Chronicle, Sanitary Record, Gloucestershire Chronicle, Reading Mercury, Hertfordshire Mercury, Weekly Free Press and Aberdeen Herald, Mining Journal, Surrey Advertiser, Local Government Chronicle, West Middlesex Standard, Local Government Journal, Le Moniteur (Paris), Le Temps (Paris), Levant Herald, Colchester Gazette, Bedfordshire Times, Ramsbottom Observer, Newbury Weekly News, Fife Herald, Lowestoft Standard, Carlisle Patriot, Sussex Daily News, &c., &c.*

The Hunterian Lectures
ON
INFANTILE SYPHILIS.

Delivered at the Royal College of Surgeons of England on March 23rd, 25th, and 27th,

BY J. A. COUTTS, M.B. CANTAB., M.R.C.P. LOND.,
PROFESSOR AT THE COLLEGE, AND PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN.

LECTURE II.[1]

MR. PRESIDENT AND GENTLEMEN,—In my last lecture I dealt with the parental sources of inherited syphilis. I now proceed to treat of the symptoms of the complaint in the infant. These symptoms are so numerous and varied and affect so many parts of the body, either separately or simultaneously, that any elaborate treatment of any single one of them is incompatible with the time at my disposal. In fact, I feel now that instead of attempting to deal with such a controversial subject as infantile syphilis in its entirety it would have been better to have restricted myself to a more thorough consideration of a selected number of the chief manifestations of the complaint. Even as it is I must pass over many parts of the subject, not on account of their lacking either consequence or clinical interest, but because time will not allow me to deal with them in a manner at all commensurate with their importance. Some others of the less debatable points I also ignore, lest I incur the charge of "demonstrating the obvious and expatiating on the commonplace."

That the symptoms of inherited syphilis may be apparent in the dead-born fœtus or in the living child at birth must now, I think, be conceded by all. The word of obstetricians, who are the only persons with any great opportunities of experience on these points, is unanimous in this respect. It is true that such symptoms as maceration of the fœtus and the like—a necessary consequence of its retention *in utero* after death—were formerly too often and falsely ascribed to syphilis. The proof that such symptoms were not necessarily dependent upon syphilis, however, in nowise detracts from the testimony of the better informed, who have found uncontrovertible evidences of syphilis in the viscera, bones, and other organs of still-born infants. It is unnecessary, however, to dwell upon such cases; equally unnecessary, too, is it, I consider, to linger on the cases of infants presenting signs of unmistakable syphilis at birth. Such infants, in the vast majority of instances, are only foredoomed to die after the briefest span of life, even under the most skilful treatment and care. If recovery has taken place in infants presenting unequivocal signs of syphilis at birth, such recoveries are so exceedingly exceptional that any lengthy discussion on them would be unprofitable at the present place and time.

I have just said that infants born with unmistakable signs of syphilis speedily die. So short is their existence that few, if any, find their way to children's hospitals and kindred institutions. There is, however, one symptom of syphilis often present or commencing at birth that may appropriately be dealt with now. This is the marasmus or wasting that forms such a prominent feature in many cases of inherited syphilis. Now marasmus in a new-born child is far from being a certain proof that such a child is syphilitic. More than this, as a rule it does not manifest itself in syphilitic infants before other symptoms have cleared up the diagnosis, and in many syphilitic infants marasmus may never supervene. But still wasting may be the earliest symptom of inherited syphilis in the infant. I have known numerous infants brought to me at the East London Hospital for Children for wasting dating from birth develop other unmistakable evidences of syphilis whilst under observation. These infants have almost invariably died. Other marasmic infants whom I fancied were syphilitic have died before unequivocal signs of syphilis had possibly had time to develop. With these facts before my eyes I have on numerous occasions placed infants in whom wasting was the only objective sign on a course of mercury where the family history was suggestive of syphilis. This treatment has, I think, been attended in some cases with success, although the measure of success is not a great one. Some of these infants both gained flesh and developed syphilitic manifestations under the mercurial treatment. Others, whilst improving under mercury, developed no further syphilitic symptoms, owing possibly, I thought, to their abeyance under treatment. But early marasmus in syphilitic infants is of such grave import that treatment, let this be as early as it may, can claim but few successes.

The marasmus I have just mentioned is that present at birth or commencing soon after it. Such cases form but a small minority of those where marasmus plays a prominent part in inherited syphilis. Most syphilitic infants are plump and well nourished at birth and usually exhibit no trace of their complaint until a month or so later; then marasmus is apt to develop simultaneously with snuffles and rash. These last may disappear under mercury, but the marasmus is prone to persist and death may result from it at a period when all the more characteristic symptoms of syphilis have passed away. In other cases of undoubted syphilis a fatal marasmus may delay its appearance until months after that of the specific symptoms proper. It is in hand-fed infants, however, that marasmus has its most frequent and pronounced occurrence. Breast-fed infants, if specifically treated, usually escape it. It is only in such marasmic infants, I am inclined to agree with Henoch, that the peculiar *café-au-lait* tint of skin appears which Trousseau described as characteristic of cases of inherited syphilis in general. With Henoch and some other writers, too, I am at one in regarding marasmus as the most important factor in prognosis in the complaint. Other points that have been laid stress upon by some authorities, such as the early appearance, amount, and character of the eruption, the extent of the involvement of the viscera in the complaint, are, in my opinion, but seldom of the same prognostic significance as wasting. Henoch practically sums up the question of prognosis with the assertion that wasting infants die but well-nourished ones recover. Many wasting syphilitic infants, if they do not actually die from an obstinate and progressive asthenia, are very apt to do so from some intercurrent disease, such as collapse of the lung or diarrhœa, which they might have escaped or recovered from had they possessed greater vitality.

Thus far, except when it was present at birth, I have only treated of marasmus in connexion with syphilis in cases where the diagnosis of the latter was confirmed by the more unequivocal symptoms of the complaint. Cases where these last can be adduced in confirmation, however, in my opinion are far from being the only ones where an association between infantile syphilis and wasting can be traced. I have seen numerous infants in whom the only objective sign has been an obstinate wasting, and where the family history alone has been inferential of syphilis. Such cases occur in infants of any age, from that of three or four months upwards. The question arises as to how far it is justifiable to regard such cases of wasting as syphilitic where there are no direct evidences of that complaint beyond, possibly, the family history. The majority of authorities would, I believe, protest against such an assumption as unjustifiable from the absence of the more characteristic symptoms and as unduly and unnecessarily extending the domains of syphilis to unknown limits. Accordingly, whilst in most descriptions of inherited syphilis wasting is mentioned in connexion with other symptoms, it is in but few that it is treated as possibly the only manifestation of the complaint. For my part I can see nothing unreasonable in the diagnosis of syphilis in many wasting infants in whom there is an entire absence of specific symptoms, and in this contention I am happy in being supported by the majority of my colleagues. Snuffles and rash and other symptoms may be very evanescent, occasionally missed, and even when marked may disappear with doses of mercury totally inadequate for the cure of the complaint. Again, the first appearance of specific symptoms may not occur for many months later than the majority of text-books allow. Nowadays, moreover, we are even told that the manifestations of inherited syphilis may be retarded until puberty or many years later still. In numerous ways, then, it may well happen that one may be frequently called upon to treat a case of syphilis in an infant in whom the only noticeable symptom is obstinate wasting, and in

[1] Lecture I. was published in THE LANCET of April 11th, 1896.

Digitized by Google

whom there is a totally negative history as to more unequivocal manifestations both in the present and the past. Dr. Donkin is, as far as I know, the only writer who has deemed such cases worthy of separate description, and he has done it so graphically that I need not go over the ground again. These cases of syphilitic atrophy are peculiar, he considers, in that they are not attended by any noticeable amount of diarrhœa or vomiting, and I agree with him in this and in his estimation of them as a large and important class that has not received sufficient attention at the hands of the profession.

The result of specific treatment cannot be applied as any fair test as to the syphilitic nature of such cases. Syphilitic infants with atrophy generally die, whether such atrophy date from birth or many months later, and whether treated with mercury or not. In some few cases I think I have succeeded in checking the wasting by means of that drug. In one or two younger infants, moreover, the use of mercury seemed to bring out other and more certain signs of syphilis beyond the wasting. The improvement in nutrition produced by the drug appeared to allow the production of these other syphilitic symptoms in infants previously too reduced in vitality for their manifestation, but their appearance with the administration of mercury may have been mere coincidence. The failure of mercury in infantile syphilis where atrophy is a prominent feature is readily accounted for by the post-mortem revelations in such cases. These show that the atrophy is by no means limited to the external parts under observation, but that it involves the internal organs at the same time. In many such cases the small intestine is found to be almost practically deprived of its mucous and muscular coats, being little more, in fact, than a semi-transparent tube of peritoneum. To a less degree the stomach and large intestine suffer from the same destructive change. With this atrophy of the secretive and absorptive surface of the intestinal tract it is evident that no satisfactory digestive processes could possibly take place. The liver, too, in many instances is found markedly fatty, and this probably assists in maintaining the failure of nutrition. The condition of intestine I have just alluded to is found in other cases of atrophy besides those arising from syphilis, but it is in these latter, I believe, that it finds its most frequent and pronounced appearance. Dr. Donkin alludes to it in his work on Children's Diseases, but I know of no satisfactory account of it in the leading pathological treatises. Here I may say that this is the only abnormal condition of intestine that I am personally acquainted with in inherited syphilis. At numerous necropsies I have seen nothing resembling the gummatous indurations of the mucous and muscular coats or of the condylomata and ulcerations occurring in Peyer's patches, described by Oser, Jürgens, and others. The atrophic condition I have mentioned is amply sufficient to account for the mortality in such cases. Mercury may be capable of combating the syphilitic diathesis accountable for the condition, but it cannot replace the wasted glandular intestinal structures on which nutrition depends.

In an apparently healthy infant, presenting as yet no signs of the parental disorder, I think it will be admitted that a mercurial course as a preventive or precautionary measure is inadvisable, if not unjustifiable. This being so, then the limit of time of possible onset of symptoms is no unimportant question, not only on account of relieving parental anxiety, but of releasing the infant from the stricter forms of medical supervision. A great diversity of opinion as to the limits of time in which initial symptoms are possible occurs amongst authorities. On two points, however, all observers are agreed, these being that in the majority of cases symptoms appear in the second month of life, and that their primary manifestation is exceptional after the third month has expired. All experience agrees on these points and statistics amply confirm them. Kassowitz, indeed, would seem to doubt whether the primary manifestation of symptoms is ever deferred beyond the third month. Dr. Radcliffe Crocker asserts that the initial symptoms are never delayed beyond the sixth month. Henoch writes: "After the second, or still more after the third month, it is rare for them to appear for the first time; and when they occur still later it is always doubtful whether it is not a case of recurrence or of direct transmission." With these last-named writers I cannot agree. I have not infrequently seen infants where snuffles and rash had primarily manifested themselves much later in the first year of life than the sixth month, and one or two where symptoms had been delayed until the second year. Of course, I may be told that such cases were those of a relapse, and that the first appearances of the complaint had been missed. Such an assertion is equally easy to make as hard to disprove. I would only say that in my experience relapses of the skin affection are somewhat rare in the later months of infancy, the common expressions of a relapse at such times being the presence of mucous tubercles or condylomata. If we may believe, moreover, in the reality of a "syphilis tarda," so commonly accepted now, then I can see no inherent improbability in the first manifestations of the complaint occurring at a much later infantile age than is usually taught. Dr. Donkin has already written to the same effect, and I gather that others are now inclined to extend the limit of time during which initial symptoms are possible to at least twelve months from birth.

The first obvious manifestation of inherited syphilis is usually the well-known snuffles. This generally precedes any affection of the skin, and in only a small minority of cases is the skin eruption simultaneous with, or anterior to, the snuffles. It is only in very exceptional instances, too, that the swelling of the nasal membrane causes distress and difficulty in sucking before the snuffling develops. Snuffles, which usually precedes all other symptoms, may also long outlast them. A few doses of mercury may cause the disappearance of all skin eruptions, but snuffles may persist for many months as the sole evidence of the complaint.

The prominence of snuffles in hereditary syphilis has often led, I fancy, to an erroneous diagnosis of that complaint from the presence of this one symptom alone. When it is marked and persistent in character I would admit a justification for the suspicion of syphilis in a large majority of cases in which it occurs. But the extreme sensitiveness of the nasal mucous membrane in infants leads to a minor degree of snuffling from many causes in cases where syphilis is out of the question. This sensitiveness of the nasal membrane persists for about the first year of life, and any undue exposure to cold may bring on a greater or slighter degree of snuffles in many infants. Its temporary character and the absence of other signs ought to be sufficient to dispel the suspicion of syphilis in the majority of such cases. There is, however, one complaint peculiar to infants where the presence of marked snuffling may mislead even the more wary. This is what Henoch has aptly named the "acute coryza of infants." In this an infant, generally after exposure to cold wind, is suddenly seized with high temperature and acute nasal obstruction, followed shortly, in most cases, by laryngitis or bronchitis. If seen for the first time towards the end of an attack, when all acute symptoms have subsided, the combination of hoarseness or voicelessness along with intense snuffling is very apt to lead to a confident, although erroneous, diagnosis of syphilis. The acute nature of the attack ought to prevent mistakes in anyone acquainted with Henoch's description of the complaint. In one case of this kind I knew dire offence given by an incautious catechising of the father which a short delay would have served to prevent.

The syphilitic affection of the nasal structures in infancy responsible for the snuffles generally leads to some broadening and depression of the root of the nose, more apparent, perhaps, than real. In most cases this is entirely recovered from, and the child grows up with a nose as well shapen as in those who are non-syphilitic. In a minority, however, a nasal deformity incurred in infancy persists throughout life. I have never in such cases noticed any undue fœtor in the nasal secretion suggestive of active bone destruction, nor have I ever learnt of the discharge of palpable portions of bone and cartilage which Diday and others write about. The explanation of the permanent nasal deformity incurred in infancy lies rather, I think, in changes occurring in the cartilage which interfere with its nutrition, and this defective nutrition is followed by arrested development. But beyond infancy there is no doubt that active destruction of the nasal bones can occur from inherited syphilis, and the usual time for this is generally from the age of four years to that of puberty. Not very infrequently, I believe, cases treated for strumous ozœna, with bone destruction, have their origin in inherited syphilis rather than struma, and I have known mercury and iodide successful in such cases where other measures have failed. In one interesting case I saw through the kindness of Dr. Julius Jacobson active nasal bone trouble occurred as late as the age of thirty-four years in a woman who was undoubtedly the subject of inherited syphilis.

The affection of the nasal membrane has little, if any,

Digitized by Google

tendency to spread to neighbouring parts, and in the early stages of infancy the pharynx generally appears perfectly normal. Diday dissents from this, as he states that repeated examinations only resulted in his finding insuperable difficulties in the way of pronouncing with any certainty as to the freedom of the pharynx in very young infants. At any rate, his repeated examinations did not enable him to find any frequent affection of the pharynx in such cases. What has been said as to the pharynx applies equally to the mouth in very young infants. Any shallow ulcerations of the mouth found in them are generally due to aphthous conditions, which are common enough in babies with no suspicion of syphilis. Henoch agrees with this, and gives useful warning against mistaking ulcers along the middle line of the palate in young infants for specific manifestations. Although in early infancy the mouth and throat are free, yet in infants some months old, whether with a relapse or not, the tonsils, fauces, palate, and buccal membranes may be the sites of a few scattered ulcers unmistakably specific in character. These affections of the mouth only occur in a minority of cases, and the infants in whom they appear are seldom less than four months old, and generally some months older than this. Fissuring of the lips, too, is a later symptom than some of the text-books allege. The infrequency of sores about the mouth and their late appearance in the disorder have, I believe, important bearings on the spread of the disease from infants to others.

Along with the sores in the mouth I have usually found mucous tubercles at the angles of the lips and often on other parts of the body where there is a combination of moisture and warmth. These mucous tubercles have been often described as one of the earliest symptoms of inherited syphilis, but this I am certain is a decided fallacy. Their real place is amongst the later signs that may occur in infancy. They are the commonest symptoms of all in relapses, and may recur from time to time, as the sole evidence of the disease, until the child is five or six years old. Henoch has pointed out the much greater luxuriance of the growth of mucous tubercles and condylomata in the acquired syphilis of children than in the inherited form, and in this my experience fully tallies. I have seen cauliflower masses of condylomata in acquired syphilis in children such as I have never seen approached in inherited cases. These mucous tubercles afford the surest evidence of syphilis where other signs are doubtful. I quite agree with Mr. Hutchinson that one well-formed mucous tubercle or condyloma is pathognomonic and an incontrovertible proof of the complaint.

The skin eruptions have been so frequently and fully dealt with by others more competent than myself that I feel any lengthy description of most of them uncalled for. My former colleague, Dr. Radcliffe Crocker, whose experience was largely gained from the same sources as my own, has indeed rendered any attempt in this direction superfluous on my part. All I would propose to do then is to take the arrangement and classification laid down in Dr. Crocker's treatise on Diseases of the Skin, and to briefly deal with the different eruptions with such comments as personal observation may seem to warrant. The most frequent sites of the eruption are admittedly the buttocks and adjacent parts, the chin and upper lip, the eyebrows, and the skin behind the ears. In exceptional and generally fatal instances the eruption may be universal over the body. Of the parts mentioned the buttocks and their neighbourhood are those most frequently affected, and very commonly, indeed, the only ones. I cannot recall a case where there was any very decided eruption where the buttocks remained free. These parts are usually also the first to show the eruption, and are the ones most deeply affected even when it is fully developed on numerous other places. Next in frequency to the buttocks as sites for the eruption come the upper lip and chin. It has been assumed that the reason for these situations being the commonest ones for the syphilitic eruption is that they are the ones most subject to irritation from contact with wet napkins and saliva or mucus. To this view I have never altogether assented. Some of the other parts commonly affected by the syphilitic eruption are subject to no irritation that would explain their prominence in this respect over others of the body. In the acquired syphilis of infants, moreover, the eruption shows no preference for the parts most affected in the inherited form, although the sources of irritation are the same in each. Other eruptions, too, confessedly owing their origin to some source of irritation, show no special preference for the sites most commonly affected in inherited syphilis. I cannot help thinking, then, that there is some selective influence at work beyond mere irritation that determines the eruption to its favourite sites, the reason of the selection lying deeper than our present knowledge can explain.

Syphilitic roseola, far and away the most common form of eruption in adult acquired syphilis, is extremely rare in the inherited disease. I have never seen an example of it in the latter. Cases are, however, related by Bassereau, Cullerier, Dr. Crocker, and others. The record of single cases by these last-named is sufficient testimony to the rarity they place upon it. Although I have never seen this form of eruption in inherited syphilis I have several times seen it in the acquired variety in both infants and elder children. When seen in these last it differs in no respect either in situation or appearance from that occurring in adults.

Although syphilitic roseola is extremely rare, another of the erythematous eruptions is the commonest of all in the inherited disease. The following account by Dr. Crocker so graphically describes it that I prefer to give it in his own words: "It consists of erythematous patches of various sizes which usually commence on the buttocks and round the anus. They may be well or ill-defined at the edge, bright coppery or yellowish red, tending to coalesce into large sheets of eruption, but generally patchy on the borders. This erythema may extend uniformly on the back and inner side of the legs quite down to the feet, including the soles, which are bright red and peeling. On the front and outer side it is still generally patchy, upwards it often extends to the loins and abdomen, and in a few cases all over the body in patches which coalesce; the whole surface is then red and desquamating on the dry parts, while on the buttocks or where it is exposed to moisture the scales are soaked off and the surface is left raw or brightly glistening. These generalised cases are very likely to die." As to the fatal nature of these cases with extensive erythema, my experience fully tallies with that of Dr. Crocker, and Henoch writes to the same effect. A papulo-squamous eruption corresponding to that of acquired syphilis is the next most common one in the inherited complaint. The following description, like the preceding one, is taken from the same source, the work of Dr. Crocker. "It consists of round superficial patches, from one-eighth to half an inch in diameter, very slightly raised above the surface, delicately scaly, with a pink or reddish-brown colour at first, but after a few days of a pale fawn tint. It may be limited to one or more regions, such as the limbs, forehead, or round the mouth, or occupy the whole body surface, usually in discrete patches, and commencing upon the buttocks, where the superficial ulceration is apt to occur from the irritation of the urine and fæces. A variety of this is a crescentic squamous eruption with a raised border, which in one of my cases began on the buttocks a week after birth and then spread over the thighs and then all over the body, forming map-like outlines on the skin, most marked on the lower part of the body and legs."

Besides this last Dr. Crocker describes three small papular forms of eruption—the acuminate, convex, and flat. The first two may be crowned with a scaly cap, a small bead of pus, and less seldom with a clear vesicle. All these forms occupy the usual sites of the other eruptions, run the usual course, and are not significant of any particular import in prognosis or severity of the disease.

Vesicular eruptions are rare in inherited syphilis and are usually preceded by other forms of eruption. The skins of syphilitic infants, too, are more prone than those of others to respond to external irritation. In this way eczema and other inflammatory eruptions may break out in syphilitic infants independently of the constitutional complaint.

Pustular eruptions are much more common than the vesicular, but, like the last, are seldom the primary ones in the complaint. Any of the previously mentioned forms under continued irritation are liable to take on a pustular character. Besides these, however, others may be pustular from the onset. Thus ecthymatous sores are far from uncommon, covered with a greenish crust, concealing sharp-edged spreading ulcers or simple excoriations. They show no preference for any part of the body and are seldom numerous, but they generally denote a profound cachexia and are of bad prognosis.

One of the pustular forms is deserving of further notice. This was first described, I believe, by Dr. Barlow, and is known as the "syphilitic furuncle," although a more appropriate name could possibly be found for it. It is of importance as being often the sole manifestation of the later stages of

Digitized by Google

inherited syphilis, and its significance in this respect is, to my personal knowledge, only too often overlooked. In its typical form it consists of an elevation of the epidermis of the size of half a hazel nut, the raised epidermis being generally of a deep purple colour. There is very slight hardening of the surrounding and underlying skin, and under the purple epidermis is a scanty secretion of ill-formed pus. If left to itself it may persist for long without the skin giving way, but under mercurial treatment it rapidly disappears without scarring. Without treatment it is apt to leave a small nodular thickening in the subcutaneous tissue, with a corresponding slight depression in the overlying epidermis. The same small nodular thickening in the subcutaneous tissue may occasionally be found preliminary to the formation of the cutaneous pustule. These "syphilitic furuncles" are most common, perhaps, in children two or three years old and are rare before the eighth or ninth month. They may appear anywhere on the body, but are most frequent, in my experience, on the upper and outer aspects of the thighs. As an indication of syphilis, when other signs are wanting, I consider them of prime importance. On two occasions my diagnosis of syphilis from their appearance alone was confirmed by the discovery of unsuspected mucous tubercles. At one time I looked upon them as pathognomonic of syphilis, but in one case I came across "furuncles," undistinguishable from those described, where syphilis could with certainty be excluded. They indicate syphilis, however, in the majority of instances, and the non-recognition of their significance by many observers is matter for regret.

Bullous eruptions are more common in inherited than in acquired syphilis. Pemphigus is one of the best recognised forms of eruption in the former. It is usually either present at birth or commences a few days later, seldom later than the first week. Dr. Crocker, however, mentions a case where it first appeared in an infant a fortnight old. It is usually confined to the hands and feet, and here more especially attacks the palms and soles. The nail beds, too, are generally affected with destruction of the nails. The situation of the eruption, mainly the palms and soles, is sufficient to distinguish it from another infantile form of pemphigus, arising from bad hygienic surroundings which shows no preference for these sites. The bullæ, too, in the syphilitic variety are flaccid and contain pus or blood; in the other variety they contain clear serum. The almost fatal prognosis attaching to pemphigus in inherited syphilis is disputed by none, and I have never known a case recover. Pemphigus in the later stages of infancy is not uncommon, but when occurring then has no connexion with syphilis in particular.

Although gummata are not, of course, confined to the skin, yet they may appropriately be dealt with now, as completing what I have to say on the cutaneous eruptions. All observers are agreed as to the rarity of gummata in the skin in inherited syphilis. My personal experience is limited to perhaps half-a-dozen cases. In only two of these did they break down forming the well-known characteristic ulcers, and even in these two there was a doubt in the history as to whether the syphilis was inherited or acquired. In the others they persisted for a long time, in spite of treatment by iodide, and this increased resistance to that drug would seem, in my limited experience of them, one of the peculiar features of gummata in the inherited form of the disease. The youngest of my patients was about two and a half years old, and the rest several years older than this. What has been said as to the rarity of gummata in the skin applies equally to gummata elsewhere in the inherited complaint. The cases I have seen of older children with destructive lesions of the palate and adjacent parts are not more numerous than the ones where gummata occurred in the skin. In more than one of these, again, the history was doubtful, and I was uncertain whether the disease was inherited or acquired. Gummatous infiltrations of the skin are of interest as being, in the opinion of Dr. Crocker and others, the only skin eruption found in the latest stages of inherited syphilis. Of this nature are probably the lupus-like conditions described by Mr. Hutchinson as occurring along with interstitial keratitis and allied disorders. These later skin eruptions are certainly rare, but I have seen one or two examples of this syphilitic "lupus" in children near the age of puberty.

One peculiarity about all the skin eruptions in early infancy is the rapidity with which they disappear under treatment and the little tendency they have to recur provided this last have been at all adequate. Mr. Hutchinson writes: "If an infantile eruption due to inherited syphilis have once disappeared under treatment, it but seldom, in my experience, shows any tendency to recur. The relapses so frequently seen in adults who have acquired the disease find no place in infants." With this opinion of Mr. Hutchinson I agree, provided, as I have said, that the treatment be efficient. During the first year I should not consider it very uncommon for the skin eruptions to disappear and relapse where the treatment had been little or none. After the first year, however, eruptions of any kind, except mucous tubercles or condylomata, are exceedingly exceptional under any circumstances whatever.

One of the most marked characteristics of inherited syphilis, as compared with the acquired form, is the early and frequent involvement of the viscera in the former, leading to their enlargement. The recognition of the affections of the abdominal viscera in inherited syphilis is not of modern origin, many of the older writers being as fully cognisant of them as those of the present time. The viscera most affected are admittedly the liver and spleen. It is, indeed, in only a minority of cases in my experience that the latter is of normal size. In 100 cases of inherited syphilis under my care I found the spleen enlarged in 62, and in 19 others its size was probably above the normal. Dr. Gee, however, only found the spleen enlarged in 45 per cent. of his cases. The splenic enlargement generally dates from birth and may certainly exist before any other symptom has manifested itself. In 92 examinations of macerated syphilitic fœtuses Mewis, cited by Mr. Hutchinson, found the spleen enlarged in 72—i.e., about 78 per cent. The fact of its occurrence *in utero* accounts for the early enlargement of the spleen to be found in living infants. In some few cases I have found the spleen enlarged in later months where I was unable to do so in the earlier ones, so that I am not inclined to regard the affection as necessarily a congenital one. The enlargement of the spleen in inherited syphilis is, I should say, very rarely carried to any great extent. In uncomplicated syphilis I have never known the hypertrophy of the spleen so great, at least in the first year of life, as to suggest any connexion between it and an associated condition of blood change, although such a connexion has been described by others. But anæmia is so common in inherited syphilis—and, indeed, in infants generally of the age in question—that it can seldom be necessary to assume any causation for it in the splenic affection. The profound anæmia and changes in the blood and bones which are sometimes found along with splenic enlargement in syphilitic infants in their second year are, in my opinion, more fairly ascribable to rickets, which almost invariably complicates the former complaint at that period. It is only in exceptional instances, moreover, that the hypertrophy from syphilis persists beyond the first year.

As far as present knowledge attains there is nothing specific in the changes in the splenic tissues that lead to its hypertrophy. The resulting pathological condition is a simple hyperplasia of all the splenic elements, and there is nothing, microscopical or otherwise, serving to distinguish this hyperplasia from that occurring in rickets and other infantile disorders. There may be, perhaps, some greater tendency in the syphilitic affection for thickening of the capsule to accompany the other splenic changes. Any conditions allied to gummata I have never seen in the spleen in syphilis. It is true that in one or two post-mortem examinations in children I have seen scarring of the splenic surface, but this fact in no way necessarily implies the former existence of anything like gummata in the organ.

After the spleen the liver is the viscus most frequently affected. The difficulties attaching to the recognition of the slighter degrees of enlargement of the liver may possibly lead to an under-estimation of the frequency of its affection. Writers of the time of Diday would seem to have regarded it as of almost universal occurrence, the last-named, indeed, somewhat fancifully suggesting that induration of the liver in the inherited form corresponded to the primary chancre of acquired syphilis. Mewis, in the statistics before referred to, in 92 syphilitic fœtuses found the liver diseased in 52 instances. The frequency with which it is found in the dead fœtus would suggest its early occurrence in the living subject, and most cases of syphilitic affection of the liver, I believe, date from birth. The changes in the organ are those of an interstitial hepatitis. Along with the increase of the interlobular tissue there is a certain amount of atrophy of the cells with destruction of the blood-vessels and thickening of the capsule. The interstitial hepatitis, as a rule, affects the whole organ, but in some cases

Digitized by Google

certain lobes, or parts of them, entirely escape or are less affected than the rest. Even with extensive disease of the organ gummata of the liver are exceedingly rare, if not unknown, in infancy. In older children I have seen them post mortem, and in two cases have known them diagnosed during life with some degree of certainty. Considering what an important part the functions of the liver play in infancy it is reasonable to suppose that such a marked change in its structure as this interstitial hepatitis entails cannot be without serious detriment to the patient. The older writers, then, were possibly right in the importance they placed on the digestive disturbances arising from syphilitic liver disease in infants, and it may be that we do not sufficiently regard them. Marked enlargement of the liver and spleen is certainly an unfavourable factor in prognosis. But symptoms directly chargeable to the affection of the liver are extremely rare. A case recorded by Depasse is, as far as I know, the only one where ascites was clearly connected with syphilitic disease of the liver in an infant. Jaundice is much more frequent, but still a rarity considering how frequently the liver is diseased. Such jaundice, I believe, almost invariably dates from birth and is generally slight in amount, but if the bile vessels be involved in the liver changes may attain a high degree of intensity. Whether slight or intense, jaundice in infants arising from inherited syphilis is generally fatal. I have known several instances of it, all fatal, and Henoch records others where along with the jaundice he found hæmorrhage into the stomach from obstruction of the portal vein. Henoch, too, mentions the case of a syphilitic woman who bore three infants who all died soon after birth from congenital jaundice. As the effect of treatment, or independently of it, the enlargement of the liver disappears or largely diminishes during the first year of life. In some instances, however, the enlargement lasts for years. I have known two children eight or nine years old, with a clear history of inherited syphilis, in the East London Hospital for Children, in whom there was ascites with the enlargement of the liver, and where what were taken to be gummata in the latter could be felt through the abdominal wall. One case required repeated tapping, but both finally recovered under treatment with mercury and iodide.

Since Dubois first described a syphilitic affection of the thymus gland in 1850 many, if not most, writers have concurred with him in recognising a similar disease of that viscus in inherited syphilis. It is claimed by some that the thymus gland is the earliest of the viscera to be attacked and that it may even be the only one to show the syphilitic taint. Dubois described two varieties, or rather grades, of this syphilitic affection of the thymus. In the first the organ is but little, if at all, enlarged. On section it is found studded with cavities varying in size from that of a pin's head to that of a pea, from which a yellow, pus-like fluid exudes. In other cases no visible cavities are found, but the same fluid can be made to exude in drops by squeezing the gland. In the second class of cases the organ is considerably enlarged, and cavities as large as a walnut may be found containing the same yellow fluid as in the first class. This fluid, Diday states, had been carefully analysed, and was found to bear all the physical properties and microscopical tests of pus. Without at all wishing to deny a syphilitic affection of the thymus, I would beg to state that a further proof of its reality is needed than that furnished by Dubois and his successors. I have seen the condition of thymus described by Dubois in syphilitic infants, but more often in infants in whom there was no reason to suspect such complaint. In one infant who died from croupous pneumonia, and who had been perfectly healthy until the commencement of the fatal illness, I saw the thymus immensely enlarged and containing a cavity filled with about half an ounce of the yellow fluid. I have never analysed this fluid, but to me the naked-eye appearances of it are not identical with those of ordinary pus. Since preparations of the thymus, too, have found a therapeutic use I hear that the manufacturers have to reject a fairly large percentage of the glands supplied to them owing to the presence of these fluid-containing cavities. It is in cases of inherited syphilis, possibly, that necropsies on very young infants are most often performed and where special attention is paid to the state of the thymus. Were necropsies as regularly made on very young infants dying from other causes than syphilis, and equal attention paid in them to the state of the thymus, I have a suspicion that the cavities in question would be found as often in these cases as in the syphilitic ones. On these grounds, then, I feel justified in my belief that up to the present the involvement of the thymus in inherited syphilis is at least not proven.

What has been stated as to the thymus applies also to the pancreas. Many writers describe a syphilitic affection of this latter in the inherited forms of the complaint. As far as I can gather the chief reason for the belief in such an affection has been an unnatural hardness in the pancreas. Now I have seldom attended a necropsy on an infant a few months old without being struck with the much firmer consistence of the pancreas than that obtaining in the case of older children. It is, I believe, a physiological and not a pathological condition and due to the active developmental and functional changes taking place in the viscus in early infancy. Before assuming, then, the reality of a syphilitic affection of the pancreas I consider that further evidence is necessary beyond a mere increase in the consistency of the organ.

An Address

ON

THE NEXT GREAT ADVANCE IN ANÆSTHESIA; INCLUDING A NEW EXPOSITION OF COMMON SENSIBILITY.

Delivered before the Society of Anæsthetists on March 19th, 1896,

BY SIR BENJAMIN WARD RICHARDSON, M.D., F.R.C.P. LOND., F.R.S.

MR. PRESIDENT AND GENTLEMEN,—I remember no event in the course of this century that ever filled the public mind with greater wonder than did the discovery of anæsthesia fifty years ago. It was not altogether an unexpected discovery, for many men in the background of history, as we may say, had for ages been working at it; but the general mind had become primed with the idea that pain was a necessary part of creation; that it entered the scheme of nature as a necessity; and that to try to abolish it would be sure to be a failure. The first part of this objection was urged after the discovery of abolition of pain had become a successful fact, and the wonder, altogether, has not passed absolutely away even in the present hour. At this time, however, we are confronted with a new difficulty; we are hearing week by week about the deaths that are taking place through anæsthesia. At first the deaths were very few, and had it been otherwise, that is to say, had there been many deaths previous to that of Hannah Greener, which occurred at Winlaton, near Newcastle, on Jan. 28th, 1848, anæsthesia would probably have died out as a practical part of surgical science. As it happened, a rare death from it did not materially affect the process of anæsthesia, and it is not until now, when the process of administration has become all but universal, that we find the public, as well as the professional, mind becoming astonished and perplexed at reading of the frequency of the occurrence. I do not know that there are more deaths now amongst those who take chloroform than there were in the early days of which I have spoken, for I remember very well, at the time when Hannah Greener died, a practitioner named Mr. Robinson, who lived at Haverhill in Essex, telling me privately of a similar disaster that occurred to him in his own practice and that was never made public, the tendency in those days being less strong in the matter of publicity. As time passed away the tendency to publish such details as those noted above became more and more marked, so that in the time of Dr. Snow we had such a number of deaths collected that he was able to announce no fewer than fifty, a number which included all that he was himself acquainted with from administration, but which did not account for two deaths, which he himself saw, from amylene. Snow collected his facts about the year 1857, and I published them from his manuscript in the following year 1858, anæsthesia having been in use in England for a

Digitized by Google

period of about twelve years. It looks, therefore, as if we only recorded five chloroform deaths a year for ten years or a tenth part of those recorded in the year 1895.

A few years after the death of Snow I made a tour through England and collected facts of the deaths which had occurred in various parts. I visited hospitals in which not less than 17,000 administrations had occurred without a death, but as I went on the deaths continued to increase on my register, not depending, as far as I then understood, on the hospital, the operator, the patient, or the mode of administration, but on accumulation of numbers of cases, so that I was brought to the conclusion in the years 1865–66 that deaths ought to be reckoned as one in every 2500, a figure which has been very particularly relied upon since I calculated it out, and which, I take it, is very close to the truth up to that date. It is not extremely difficult to account for this figure, quite apart from its having been based originally upon recorded facts, for it seems that there is always in a community a certain number of persons who, from one cause or another, are ready to die under unfavourable circumstances. I have named this class of mankind the "morituri" because of this readiness to die, and I estimate that there never exists a collection of 3000 middle-aged people but that there is sure to be one who is possessed of some fatal tendency which might lead to the occurrence of death, so that the administration of anæsthetics does not necessarily modify or intensify the chances of death amongst them. This is satisfactory as far as it goes, but at the same time, as all are not "morituri," it does not do away with the necessity of inquiry as to why death appears in the proportion named from anæsthesia. Neither does it limit our investigations into a mode of killing pain that could not possibly at the same time kill the person who would have to be anæsthetised. Dr. E. Andrews, the Professor of Principles and Practice of Surgery in Chicago Medical College, summed up his observations in 1870 almost in similar figures as mine. He calculated the deaths from chloroform as one in 2723, but he added other figures. He said that the deaths from sulphuric ether were one in 23,204 administrations; from mixture of chloroform and ether one in 5588; from bichloride of methylene one in 7000; while to nitrous oxide he gave the credit of not one death in 75,000 administrations.

Without staying to enter into any analysis of these figures we are obliged, as practical men, to ask the reason why there should be any deaths at all from anæsthesia, in which question we shall include why there are so many deaths from one anæsthetic and so few from others. If it be true that there are no deaths in 75,000 administrations of nitrous oxide there can be no reason, whatever may be our theoretical generalisations, why there should be so many from other anæsthetics except there be some error either in the anæsthetic employed or in the mode of giving it. Some will argue that season, temperature, and all the meteorological conditions are favourable to death in the case of one anæsthetic and not in another; but this is hardly fair, because we calculate, or rather include, the same facts in one anæsthetic as we do in another, and we, therefore, ought to have the same results from one as from another. If I administer nitrous oxide as many times to 2500 different people and have no death, and administer chloroform to the same number of people and have one death, it is clear that, *ceteris paribus*, there is something in the nature of the anæsthetic that determines the result; or if I administer ether to 23,000 persons with one death, and administer chloroform the same number of times with more than nine deaths, which is about the estimate, it must turn out there is something in the composition of the two substances—ether and chloroform—which determines the result. It may be urged by other argumentatists that whilst there is a distinction between the composition of the two substances which yields such varying conclusions, a great deal has to be said in favour of the worst of them because of other virtues they possess. Thus the most fatal of the anæsthetics may have the virtue of being rapid in its action, convenient in its administration, and, while the patient is unconscious, certain in its effect. I have heard this urged ever since I can remember, and I recall, as if they were only at this moment spoken, the words of Snow himself to the effect that chloroform was to ether like the lucifer match to flint and steel; he preferred its readier application and accepted its risks. But this, I think, is not a good argument, for the reason that it only requires more industrious examination and consideration to obtain an agent which shall be just as safe as ether, or even as nitrous oxide, and yet shall possess all the qualities and characteristics in administration that chloroform possesses; that shall be as rapid as chloroform, as convenient, as certain, and, at the same time, as safe as any other.

This particular thought has been on my mind for half a century, and though I have not been able to solve the difficulties as I could have wished, they are what I would still like to press forward, and which I would rejoice to leave to the investigation and exposition of the future man who shall solve the problem. I perhaps cannot do better in this place and at this moment than point out what these difficulties are, and the mode in which I have laboured to overcome them, because in so doing I may lead someone else in the direction in which I have not had time to continue myself.

In promoting anæsthesia the thing we do is to make the person about to be anæsthetised imbibe and take into his blood and nervous system an atmosphere which shall so entirely change his whole nature that he shall go to sleep, and shall lose all that sensitiveness of his nervous system which, under ordinary circumstances, causes what is known as sensation, and in extreme circumstances produces what is called pain. A double or duplicate action is thus implied—one of sleep and one of insensibility. According to our present knowledge sleep and insensibility happen to be united, but there is no definite reason why there should be such unity. It is not absolutely necessary that there should be sleep, and impossible as it seems to be that a human body should have no consciousness of the surgeon's knife and yet be awake, there is no absolute reason why consciousness and insensibility should not be separated. We see, in fact, this phenomenon. I have known a person suffering from what is termed anæsthetic hysteria, who had no sensitiveness in any part of the skin, and who was yet able to carry on a conversation and to take food the same as if there was perfect sensitiveness. Moreover, I have had under my observation a patient suffering from partial paralysis, motory and sensory, who would not have suffered at all if the affected part of his body had been cut away, but who yet would have been conscious of all that was going on round about him. I have also met with some drugs which produce a partial insensibility and yet do not materially affect consciousness, and *vice versâ*. It is, therefore, not too much to expect that we may find agents which do really destroy sensibility without materially interfering with consciousness, and this is the direction in which we have to explore, a direction I have myself constantly been on the look-out for, but have never perfectly succeeded in completing. What the atmosphere is we want to introduce into the body which shall destroy sensibility, and, at the same time sustain consciousness, is the thing we have to look for, and we have also to consider what condition of the nervous system is induced which interferes with one function and does not interfere with the other, or *vice versâ*.

The first and most telling effect is that we can put the body in such a condition as absolutely to destroy all feeling and yet apparently not touch so as to injure those centres by which we think and act. This is precisely what we do under the influence of cold; we put a part of the body into such a condition that there shall apparently be nothing going on in it whatever in the way of chemical change; we freeze such a part and we say that it fails to receive those vibrations which we call sensory or sensational. We see a surgeon put a knife into such a part, and though we be the patient ourselves we do nothing but look on, nor do we from any local manifestation become aware of the most refined dissection or manipulation which the surgeon is effecting. When this is the fact it is certain that we are rendering benumbed or practically dead those parts of the nervous system which ordinarily are the seats of impressions which signify the person's sensibility, while there has been no injury to the other parts of the nervous system which convey to us intelligence of the vibrations leading to the manifestations of consciousness. This is a most singular circumstance, showing as clearly as can possibly be shown the duality of the animal system; the truth that duality can be distinctly separated, and that what we actually want to do is to find out how, through the whole system, to make such a duality and to let life, however low, continue in progress. In hibernating animals Nature, who is cleverer than we are, is apparently carrying on the very

Digitized by Google

ocess which I would define—that is to say, she is maintain- ; life without the necessary connexion of sensibility, for ave seen a hibernating animal which did not feel, and I pect that hibernation will be the final triumph of anæs- esia. I have also seen an animal become insensible during inhalation of oxygen condensed by cold, and if we could, any fortunate method, discover a plan of making perfectly d oxygen pass into the body the ends we have in view uld for the time be completely attained.

While we wait for so grand an attainment we are bound endeavour to produce a similar result by submitting the ganisation to a series of gaseous or vaporous substances ich, by their presence, shall have the power of performing task that might come from mere cold.

NATURE OF COMMON SENSIBILITY.

I feel it will be best in this paper to place before the iety the conclusions to which I have been led after a riod longer than, perhaps, has been known to any other n and attended with more experimental research. I know at in what is about to be stated I am breaking completely ay from the common dogmas of a physiological kind and advancing entirely on new ground, but this I cannot help cause I am merely following the facts that have been put fore me by Nature herself in the course of my work. I ld, then, that we live obedient to the outer world, and that e live from the outer world and from nothing else, and e always picking up its vibrations as we do its food d drink. It is usually conceived that in the body the rebro-spinal system is a kind of independent organisa- on and that all impressions are received by it and all mmands are given forth from it; and this, no doubt, ay be held in a certain way as the fact. But it is mmonly assumed that the brain is fed by the blood and at upon such feeding it exercises its own independent nctions. I do not myself accept this reading. I conceive at as we own nervous expansions like the retina, which izes impressions from without by a very simple mechanism, o we have distributed over the whole surface of the body n impressionable nervous root or expansion which receives ibrations from all the universe; that enter us in the same ay that the retina receives special impressions; that the ervous expanse distributed over us is made up of, and con- entrated into, nervous fibres, and that nerves thus formed arry to the brain the impressions we have received just the same way as the optic nerve carries the picture. hus every vibration made upon the outer surface of our odies—from the mere vibration incident to heat and ld, from the vibration incident to the merest touch, or e vibration incident to the surgeon's knife—are all athered up by the nerves from the nervous expanse and conveyed to the central organ of the nervous system. his universal expansion from which sensitive nerves spring , in my opinion, everywhere in the body where blood can enetrate, where blood can burn, and where, by burning, imal heat is generated, and can not only find its way in erve tracts, but can also yield the substance out of which e tracts themselves are formed. That the natural brain mass of nervous matter so carefully sealed up can receive l the impressions given to it, and, receiving such, make e body the companion and—it may be said—a part of l the universe, is a clear and simple proposition. is not strange that centres which can thus receive pressions can lie by and give them out in their m—acts that the nervous system performs, taking in hatever vibration is presented to the nervous expansion which it receives sensation, and giving back that with hich it is surcharged in the form of motion. The planation given tells with special effect in regard to esthesia because it conveys that whenever through the od current we diffuse over the whole nervous expanse, which vibrations arise, some substance possessing the wer of modifying natural vibration, we, by necessity, an effect. To my mind, therefore, when with the air the blood we spread, to every part of the body the air can ich, a foreign substance like chloroform or any of its allies, so modify vibration that the sense is lost to the full ent of the diffusion of the substance we have introduced. In the course of my life I have tested the effects of over nty-five different substances which are capable of passing diffusion with the blood over the universal nervous face, and I have divided these substances according to ir nature, or rather according to their constitution. rting with what I have considered an anæsthetic base, or basic element, I have followed the action of each substance and placed it under what seemed to be its true head; thus, taking carbon as a base, I have followed it through the amyl, the butyl, the benzine, the true carbon, the ethyl and ethene series, the methyl and methene series, and the turpene series. I have also, taking nitrogen and hydrogen as bases, followed the series apparently depending upon it, and by this increase have learned so truly the nature of results that, if the chemist can place before me any substance he may possess, telling me its composition, weight, solubility in water, vapour density, and boiling point, I can on pure grounds of calculation tell whether it is or is not an anæsthetic, and if it is an anæsthetic how much, according to the weight of the animal, it will take to produce narcotism; how long it would take in a given quantity, and what would be the termination of the phenomena before it escaped from the organism. I need not trouble the society with the details of these researches, but I may indicate that they have been repeatedly stated in the various papers I have read at different times; but what I would say is that no group of phenomena has ever occurred to me that has not to some degree resembled the effects arising from cold—that model anæsthetic which has already been referred to, and which seems to prevent the nervous expansion, either locally or generally, from absorbing and transmitting to the nervous fibres, which spring from it, vibrations of sensibility.

From these observations I am led to infer that anæsthesia whether local or general depends always upon the same condition, namely, the suppression of vibrations from the origins, or expansion, of the peripheral nervous fibres spread out in the membranous structures; nerves—according to my interpretation—commencing there, not terminating, and forming afterwards the nervous cords that pass and carry direct vibrations to the brain.

It seems to me also that there is a special arrangement for the commencement of the vibration, as in the act of vision, where the picture is directly imposed upon a special surface like the retina. Again, as in the case of hearing, the impression is made upon a vibratory membrane and is thus communicated to a nervous surface. Again, in regard to smell, the membrane is a nervous surface, the Schneiderian, and the impression is conveyed by special nerves rising from it; but the sensation we call feeling, which, indeed, is a sense as certainly as is seeing and smelling, is that common sensibility which springs from the vibration in the extreme termination of nerves in all parts; the vibratory movement which usually excites it being the oxidation which is taking place at every point between the oxygen of the blood and the structures it laves, a vibration easily communicable to all parts and easily transmissible from all parts to the centre through the nerves which originate in the periphery, to be reflected back again in the centre, when it is necessary, in the form of motion.

Under these observations we must consider every anæsthetic the same in action; if we freeze a part we stop peripheral vibration; if we abstract all the blood from a part we stop peripheral vibration; if we make extreme pressure we stop peripheral vibration; if we introduce some other agent locally we stop peripheral vibration; if we divide the filaments of nerves which conduct vibration we do the same thing; and, to crown the whole, if we introduce into the blood by the lungs some vaporous substance which the blood can absorb, and get that vaporous substance carried into the peripheral surface, we stop vibration everywhere and create universal anæsthesia. This propositon brings us direct to the agents which, being absorbed by the blood and carried by it over the whole system, interfere with the animal fire and suppress the vibratory origin of feeling—creating anæsthesia. It is this I have ever had in mind in considering what a true anæsthetic should be. Nitrous oxide is for a moment an anæsthetic simply, because it replaces oxygen and does not sustain universal vibration—is, in fact, an asphyxiated substance. Carbonic acid holds precisely a similar place. Ether stands practically in the same position, but with the difference that a little oxygen travels with it, so that vibratory phenomena are reduced rather than checked, and in the long list of anæsthetics which have passed through my hands I have seen not one the quality of which cannot be read off in a similar manner. Turning to chloroform, which we may still consider the king of anæsthetics, though it may be the most fatal, its action admits of ready explanation. It is quite certain to those of us who remember its origin that it came in first as an ether—the so-called "chloric ether." It did not come

Digitized by Google

from any theory as to mode of action, but simply from observation of effects; as a vapour it has the power of being slightly absorbed by blood; the blood does not take up a great deal of it, the whole mass of blood being able to absorb not more than 20 grains of chloroform so as to make a uniform diffusion. If more than this be introduced into the blood the chloroform begins to separate; its molecules begin to attract one another and form minute points or blocks, which refuse to make the complete round of the circulation, and which I have actually found in the blood as direct modifiers of its course through the minutest vessels. But when it is simply homogeneously diffused through blood itself, its properties are those of suppressing heat and interfering with the vibration which springs from the chemical change in progress. The way in which chloroform acts in this particular is, I think, not difficult to explain, and is due to one of its elements which is too heavy for the quick vibration which constitutes feeling; that element is chlorine, which forms a large part of the fluid, which is as 32 to 12 compared with the carbon, and 32 to 1 compared with hydrogen in the same quantity of fluid. No wonder, therefore, that it stops sensation and that in its presence the surgeon's knife or the burning cautery are not detected.

I have at all times seen that the chlorine has been the danger in regard to chloroform, and I once traced the direct action of chlorine in a specimen which I was administering to the subject. Fortunately, I saw this in time, and inhaling a little of the chlorine myself detected the cause of danger and did no further mischief. I have also observed that in tetrachloride of carbon, where the hydrogen is entirely removed, there were always signs of the influence of chlorine, and a great many years ago I was so impressed at these effects that I thought it would be possible to remove certain portions of the chlorine and to make a lighter compound. This led me to the employment of bichloride of methylene, which means a fluid from which one atom of the chlorine is extracted from the chloroform. The extraction is made by the action of zinc, which, in contact with chloroform, takes up a particle of the chlorine in the presence of a little alcohol, producing chloride of zinc and leaving a fluid containing a trace of alcohol with bichloride of methylene. In the first of these experiments I succeeded very remarkably, and from that time I have always administered methylene, instead of chloroform, with success. I treat with the silence it deserves the continental rumour that the great French chemist Regnault—who died on Jan. 19th, 1878—made a specimen of the bichloride, from which, in my opinion, the chlorine could not have been properly removed, and which was, therefore, fatal. I treat also with the same silence the widespread absurdity that bichloride of methylene is a mixture of chloroform and alcohol. At the same time I would never unduly press forward bichloride of methylene, first, because it is rather a difficult product to make, and, secondly, because it contains chlorine, which always has been, and is, a dangerous element. Chloride of methylene would, in fact, be a better compound to use than the bichloride, as it gets rid of two of the chlorine elements; but it is a gas, is managed with difficulty, and, again, it has the objection of containing chlorine. You will gather from these observations that the temporary introduction of a member of the chlorine series into the anæsthetic series has been from the first a mistake—a mistake which must by necessity be met in the future by the exclusion of so objectionable an element. What, then, you will say, ought to be put in its place? This is the grand question which is left to be solved. Many think that ether is sufficient; many do not think so, and it must of necessity be slower in its action because it contains oxygen. Bromine and iodine, which in many points play the part of chlorine, are objectionable on the same grounds, and all the amyl series, in which hydrogen is an important element, are objectionable because they are not easily soluble, but separate in the blood, and producing minute globules of themselves are obstructive to the course of the blood, and though I have tried them all, as well as the hydrides and olefiant gas—which is a pure hydro-carbon—I have found one or other objection against their use.

The body that has seemed to me to present the best qualities for general anæsthesia is what is called methylic ether, a substance on which I have reported several times and have administered over thirty times in surgical operations. It is an objection that it is a gas. I discovered it in 1867, and I repeat what I then said—namely, that it may be considered the safest anæsthetic that has yet been discovered, although it is troublesome to administer and would have to be condensed like laughing-gas if it were to be brought into use. It has a curious faculty of destroying sensibility before it destroys consciousness, and recovery from it is exceedingly rapid. Its effects were very well manifested in a patient to whom I once administered the gas for Mr. Brudenell Carter. The patient, though feeling nothing, was quite conscious of all that went on during the operation. I observed also—and reported—that the gas is so safe that an animal under its influence may remain breathing it for twelve minutes without dying, and, if allowed apparently to die, may be recovered by artificial respiration so long as seven minutes after the cessation of respiration—that is to say, after what appears to be actual death.

CONSCIOUSNESS AND COMMON SENSATION.

It is time now that I concluded this paper, and I do not think I can do so at any better point. Thirty years ago I showed that it was quite possible to destroy common sensation and yet not destroy consciousness, and I press this matter once again as of vital importance. In several cases where I administered the methylic ether for removing pain in surgical operations the patients, when quite insensible to pain, were so conscious that they were able to obey every request asked of them, and in some instances were even anxious to reason, stating that they knew what was going on, and arguing that they were not ready for the operation because they were sure they should feel pain. Nevertheless, in this state of mental activity they were operated upon, and afterwards, while remembering every incident, were firm in their assertion that they felt no pain whatever during the operation. One patient who sat for the extraction of two teeth selected the tooth to be first extracted, putting her finger to it, and afterwards rearranging her position for the second removal. To the looker-on it seemed, in fact, as though no change in her life had occurred, yet she affirmed that she was sensible of no pain whatever; and several other less striking, but hardly less singular, examples came before me. We may then, I think, fairly assume that in course of time we shall discover manageable and certain anæsthetic substances which will paralyse sensation only, leaving the muscular power unaltered and the mental little disturbed; and we gather from this either that in the cerebral hemisphere there is some distinct and simple centre of common sensation which may be acted upon by certain agents without involving all the cerebral mass, or that the peripheral nervous matter may be influenced without involving the other portions of the nervous system. On the whole I incline to the view that the action of those agents which destroy pain before they remove consciousness, is primarily on the peripheral system; for we know from the process of local anæsthesia that it is easy to destroy sensation at the extremities without destroying or even interfering with consciousness, while those who have inhaled the vapours which destroy common sensation before interfering with consciousness describe the experience of a numbness and insensibility in the extreme parts of the body.

That which we medical men most require is an agent that shall be easily applied, and shall admit of being so applied generally as to induce insensibility to pain with or without destruction of consciousness, as the case before us may demand. There are many minor surgical operations for which consciousness need not be destroyed, although pain ought to be; there are other operations in which the consciousness of the person operated upon is of great service to the operator; and there is a third class of cases in which it is essential to suspend both sensation and consciousness. Now those agents which first destroy common sensation can always be pushed to the extent of destroying consciousness, so that if we could get a perfect agent of the kind we should have the full requirements in our hand. Up to the present moment we have been content with two classes of agents, one which destroys consciousness and sensation at the same time; the other which locally destroys sensation and has no further influence. I look hopefully for a method in which, by means of a single agent, we shall be able at will to suspend common sensation alone, or to exalt the process into suspension of consciousness. When this object is attained with safety and facility the science of anæsthesia may be considered as perfected.

Postscript.

As I peruse the above MS. on this day, March 18th, 18[illegible] I recall with great regret that the fatality from the administration of chloroform does not show any signs of decrease

Digitized by Google

and that the patients in whom the deaths occur are, as heretofore, often sufferers from trifling ailments. I also notice that the symptoms of deaths are very rapid; that the amounts of chloroform administered are exceedingly varied, and that the mode of death seems usually to be the same as that in which Hannah Greener—who was the first to succumb to chloroform—died, some fifty years ago. I observe, further, that in one of the deaths from chloroform, which took place at Dudley, the patient was a healthy young man who submitted himself to the narcotic for the operation of tooth extraction; that he was fully examined beforehand and gave no indications of disease; that he inhaled with readiness; that the operation was performed dexterously; that the chloroform was perfectly pure; and that the post-mortem appearances afforded no evidence of the cause of the collapse. These frequent recurrences of death support the conclusions already advanced as to the danger attendant upon the reception of all bodies of the chlorine series, and they also suggest that every specimen of that series should be administered slowly in small quantities, so that narcotism should be induced by eighteen to twenty minims at the most. The question of small and slow administrations is one of the most critical, and makes a distinction between surgery proper and anæsthesia, which is of vital importance. When there was no anæsthesia, surgical art was, of necessity, predominant. The surgeon was the most brilliant man who could operate most quickly, and, with a steady nerve, could perform any possible operation. As a result of the work of ages it became natural that surgery should still in our days hold the first place, and that although in nineteen cases out of twenty the surgical operations might be mere bagatelles as compared with the production of unconsciousness by a narcotic agent, it has required a long time and a hecatomb of deaths for the fact to be demonstrated that the work of the anæsthetist calls for the first and most serious consideration. The old conception has continued to keep surgery in its original state and to cause anæsthesia to be looked upon as a mere adjunct. There is another element of danger in respect to the question of time. As in surgery brevity was the primary process, it came to be expected, both by the public and by the profession, that brevity in anæsthesia ought to keep pace. Thus during an operation the surgeon expects the completest insensibility, and, not getting it, spurs on the anæsthetist to be as brief as he wishes to be himself—a direction which the administrator, by habit, is as willing to obey as if he were simply an adjunctive aid. In the future all this must be changed. The anæsthetist must know and feel that he must be left quite independent in producing painlessness, while the surgeon, however brilliant, must follow his lead and not think of operating until the patient has been pronounced by the administrator safe, senseless, and ready for the knife.

LITHOTRITY IN CASES OF STONE: SIMPLE AND COMPLICATED.

BY HERBERT MILTON, M.R.C.S. ENG.,
PRINCIPAL MEDICAL OFFICER, KASR-EL-AINI HOSPITAL, CAIRO.

LIKE most surgeons called upon to treat a large number of calculous patients I consider that Bigelow's operation has proved itself to be in expert hands capable of yielding the best results in all simple cases of stone in children and in adults. I do not intend, therefore, to enter into any discussion as to the relative values of the different operations practised for the relief of vesical calculus, but simply to record my experience of lithotrity, to describe a few modifications which I have found useful in its practice, and, finally, to consider how far it is capable of maintaining its superiority in the presence of the complications most frequently met with in cases of bladder stone. I have in the title of this paper divided cases into two categories—simple and complicated. By a simple case I mean a stone of moderate dimensions and hardness situated in the bladder cavity of an adult or adolescent patient whose urethra is of at least normal dimensions, and who is free from any other important disease either of the urinary or of the general system. By a stone of moderate dimensions and hardness I mean one not exceeding 50 grammes (about 2 oz.) in weight and capable of being crushed by a No. 12 or 14 lithotrite. By a urethra of normal dimensions I mean one which will take without strain a No. 12 or 14 catheter of the English scale. Other cases I consider to be complicated, and it is evident, therefore, that a large proportion of all stones met with enter into this category. The complications to which I propose to refer are those arising from: (1) the size of the stone and its hardness; (2) its position; (3) the incomplete development of infancy and childhood; (4) old age and its associated degenerations; (5) various pathological conditions of the urinary system; and (6) the general condition of the patient. My remarks are based on the records of 209 cases contained in the following tables.

Table I. contains every case of stone in the bladder that I have operated on since the beginning of 1892 up to No. 200 with two exceptions. The first case not included occurred in a boy admitted with typhus fever, during the progress of which he was attacked with retention of urine. On passing a catheter a stone was detected, and it was decided to operate in order to prevent the urinary retention and other symptoms of stone from aggravating his disease. The stone was small and the operation (lithotomy) very simple; but the boy succumbed three days later to the typhus fever. The second case not included died under chloroform from chloroform poisoning. I had performed a few stone operations before 1892, but unless there was some great peculiarity had kept neither notes nor stones. In the beginning of that year I took over the whole of the operations for stone in the Cairo Hospital and commenced my collection and my record. In composing the tables I have taken advantage of the principle of the magic square. Having classified the cases according to the various conditions usually considered important in stone operations, age and sex of the patient, nature of operation and its result, the size of the stone and its chemical composition, I have been able, by adopting this principle, to show the relation of each one of these conditions to each one of the others. Under the heading of age I have divided my patients into the three periods of youth, middle age, and old age, allotting thirty years to each of the first two periods. The usual tendency in modern classifications has been to divide cases into children and others, or in the case of one of our greatest operators into old men and others. My experience has been, as with other surgeons, that the older the patient the more dangerous the operation becomes, with the proviso, however, that the age of the patient does not depend solely on the number of years he has lived. The other headings require no special notice, but I would draw attention to the columns showing the composition of the stones. It is remarkable that in so small a collection there should be so many examples of the rarer constituents. The analyses are above suspicion, having been made by a first-class analytical chemist, who has examined every stone for every possible constituent. I think that the remarkable results are due to the accuracy of the examinations, many constituents being detected which a more superficial examiner might have missed. In any case the presence of two stones containing cystine, of one composed almost entirely of urostealith, and of one containing xanthine in such a small collection is not in accordance with the experience of other operators. It is difficult to determine what proportion of the above cases should come under the category of "simple," for the reason that my records are not accurate enough as to the condition of the urinary and other organs, and I cannot, therefore, say what proportion of the simple cases have been treated by each of the various forms of operation. It will be seen, however, that 141 of the patients have been treated by urethral lithotrity, with a total mortality of 3. In one of three fatal cases the patient was more than eighty years old and had a stone of nearly two ounces; in the second the patient's age was about fifty-five, and his condition was complicated by fœtid cystitis in a very sacculated bladder; while the third patient was thirty-five years old and the subject of advanced kidney disease.

In performing lithotrity I have always carried out the method recommended by Bigelow—viz., complete evacuation of the stone at a single sitting. The patient has been in all cases prepared by one day's milk diet followed by a brisk purge. The operation has always been performed under chloroform narcosis. It is quite needless for me to describe in any way the technique of this operation, which has been brought to great perfection in many parts of the world, and more especially at the hands of some of our Indian surgeons. I doubt whether any other method will or can ever give in

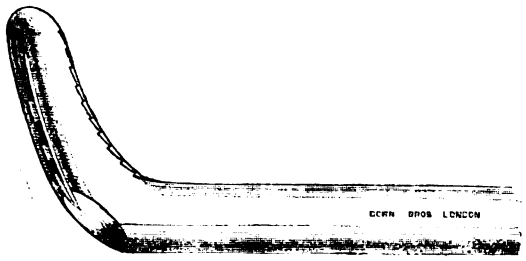
simple cases better results than this has given and it seems almost futile to attempt to modify it. I have, however, been induced to attempt a modification which, though unlikely to be attended by better results in simple cases, may be of service in a complication to be referred to later, and may, perhaps, recommend itself to the patient and surgeon from the simplicity and ease with which it may be carried out. Bigelow's operation necessitates the introduction into the bladder of two different instruments—the lithotrite and the evacuating tube. Each of these may require to be introduced several times before all the fragments are brought away. My object has been to construct a single instrument combining the functions of the two, and therefore capable of completing the operation with a single introduction. After the expenditure of much careful labour and the exercise of much ingenuity Messrs. Down Brothers have manufactured for me a lithotrite (Figs. 1 and 2) which partly, at all events, fulfils both those functions. This instrument in general

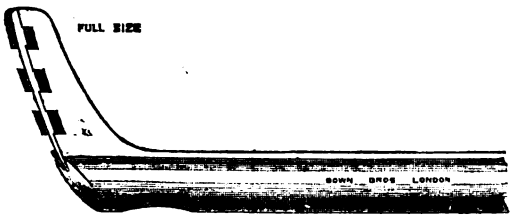
FIG. 1.



Distal end of lithotrite.

shape and appearance resembles an ordinary lithotrite. The female blade is, however, hollowed out to a larger extent than usual, so as to receive the tube which is attached along the whole length of the male blade. This tube presents

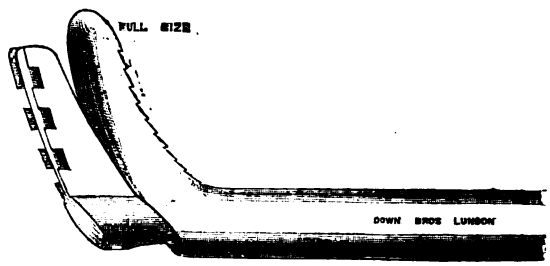
FIG. 2.



Distal end of male blade.

on its lower surface, just below the jaw of the male blade, a large opening, beyond which its end is filled up as in an aseptic catheter. The tube, continued through the centre of the screw, expands beyond the handle (Fig. 3) to receive the evacuating syringe. The male and female blades are so adjusted that when it is desired to aspirate the male jaw can be made to pass right through the female jaw, protruding to the extent of about four lines (Fig. 4) sufficiently to expose the eye of the male blade beyond the heel of the female.

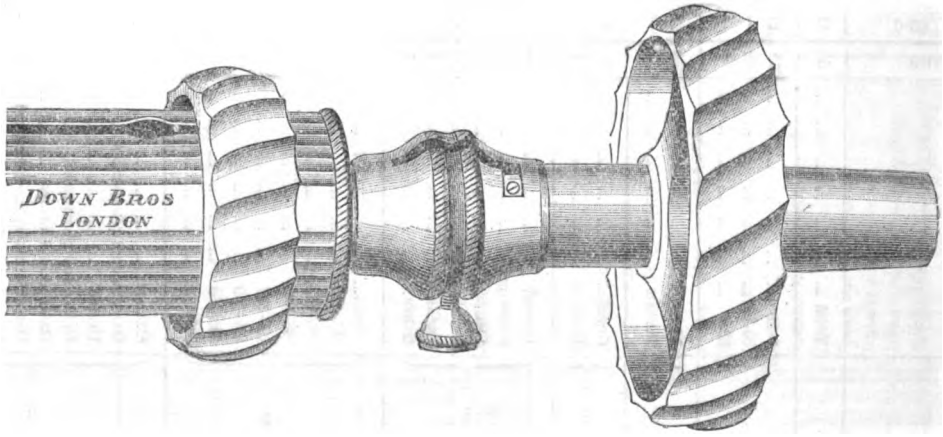
FIG. 4.



Protrusion of male blade through female during evacuation.

A stop situated in the handle of the instrument prevents this protrusion during such time as the instrument is being used for crushing. The reunion of the two functions of crusher and evacuator limits, as might be expected, the range of each. The instrument is of necessity weaker than an ordinary lithotrite of the same calibre. This has to a certain extent been remedied by the addition of a solid steel core, which, passing down the whole length of the tube, greatly adds to the strength of the instrument when crushing. This lithotrite is capable of crushing, and has crushed, a fairly hard calculus of 50 grammes; it must, however, always be used with great care and delicacy when dealing with such stones. The vast majority of stones, however, fall short of these dimensions and are such as to be quite readily crushed by this instrument. It is, moreover, chiefly in the case of old subjects that I think this method is likely to be most useful. When dealing with such cases it becomes of vital importance to treat the prostate as delicately as possible, and it is here that the great advantage of the single introduction will be found to lie. In these subjects, also, the stone, although apt to be large, is generally phosphatic in nature and friable, and under such circumstances the lithotrite is capable of dealing with quite large masses. As an evacuator, also, the instrument is less efficient than an evacuating tube of a similar gauge. The bore of the tube of a No. 14 evacuating lithotrite is equal only to that of a No. 11 or No. 12 catheter. The operation is necessarily, therefore, more prolonged, as the fragments must be broken up more finely. The instrument has, however, advantages which I think more than counterbalance these drawbacks. The single introduction which alone is necessary greatly diminishes the injury done to the urethra and prostate. In a healthy adult this has not the same importance as in an old man suffering from a large prostate. It is, however, especially in the latter class of cases that lithotrity becomes attended with danger, and it is in these cases that I think the modification is most likely to be of use. Secondly, it enables the operation to be made without anæsthesia where there is no special difficulty and where the patient prefers to avoid the administration of an anæsthetic. The operation

FIG. 3.

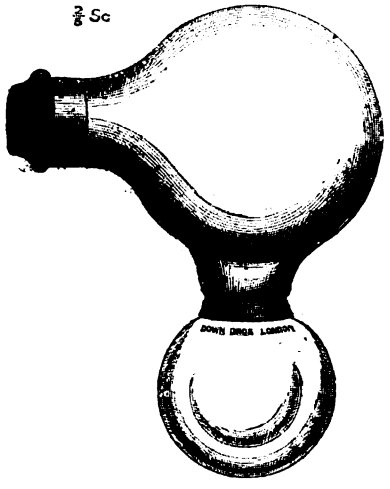


Handle of lithotrite.

Digitized by Google

without anæsthetics, however, requires very careful and very delicate manipulations, and should only be attempted when the patient objects to the narcosis or when there are other reasons against it. It must be limited further to cases in which the stone is small and easily friable. After the short experience I have had I would say that while advocating the evacuating lithotrite for use in the removal of small stones I can adduce no evidence to show its superiority in such cases to the ordinary instrument, and that I do not think it possible that its use will give any better results than those obtainable with Bigelow's method and instruments. The only advantage that I can see for it is in the possible diminution of the necessity for narcosis. I shall refer to the use of the instrument in complicated cases further on. I wish to say here a few words as to the evacuating syringe. I have used chiefly the syringes introduced by Thompson and by Golding-Bird. Of the two I consider the latter to be preferable; it is simple in construction, easily filled, and readily used. I have lately had made for me by Messrs. Down Brothers a syringe (Fig. 5) which possesses these advantages to a still greater extent. It consists of an indiarubber syringe shaped like a pear, with two stems, the one at right angles to the other. The horizontal stem carries a vulcanite socket to receive the evacuating tube. The vertical stem terminates in a glass receptacle for the débris. There are no valves and no taps,

FIG. 5.



Evacuating syringe.

the action of gravity alone being sufficient to prevent the return of the débris into the bladder cavity. The filling of this syringe is quite simple. The hole being held uppermost, water is poured in from the tap or jug. When three-quarters full the syringe must be slightly tilted to empty the glass receptacle of air. The removal of débris from the syringe is equally simple. The orifice should be closed with the thumb and the syringe inverted, so that, the glass receptacle being the highest part, the fragments fall into the ball cavity. The syringe is then turned so that the orifice becomes the lowest part, and the débris escapes with the water, one or two squeezes serving to expedite the escape. In addition to these advantages which it shares with other models this instrument possesses two peculiarly its own. In the first place, the mounts being of vulcanite, it can be easily sterilised. This point has not received, I think, sufficient consideration, and it is very easy to see that an infected syringe might have a very prejudicial effect on the result of an operation. Secondly, it enables the operator to have full control over the movements of the evacuating tube in the bladder. This is a point of very great importance, especially towards the close of an operation, and is not possessed by any of the more modern evacuators. It may further be added that it is greatly cheaper than any other form. The manipulation of the syringe when in use is very simple. The compression should always be gradual and but little water should be injected into the bladder. The expansion of the syringe should be sudden so that all fragments are easily lifted by the current. A very slight pause should be made before each compression of the syringe so as to allow the fragments to settle into the recipient. Having used this evacuator some sixty times I can confidently recommend it to other operators. In general I would say, therefore, with regard to simple cases of stone in the bladder that by far the best operation and the one which gives the best results is lithotrity at a single sitting, and that the use of an evacuating lithotrite may be useful in some cases.

With regard to complicated cases of stone, I have already mentioned the complications I propose to refer to and shall consider them in the order given. The first is that arising from the largeness and hardness of the stone. Table II. has been drawn up with reference to this complication and contains all the stones that I have operated on whose weight has reached 50 grammes. Thirty-two of these cases are taken from Table I.; nine of them were operated on before 1892. The specimens and records of these nine cases were preserved on account of the abnormal dimensions of the stones. Being selected cases they are not admissible in the general table, but the reason for their selection makes them specially suitable for Table II. The remaining nine form a portion of my third hundred, which is not yet completed. I have fixed the minimum weight for a large stone at 50 grammes, or a little less than two ounces. This limit is of course arbitrary. My reasons for choosing it are (1) it is numerically convenient; (2) few stones reach this size; (3) in all tables, old and new, the mortality attending operations on stones over this limit rises greatly; (4) I consider this to be about the limit at which a stone can be extracted from the wound of a perineal cystotomy in an adult without bruising or laceration of the tissues; and (5) it is about this limit that the difficulties of lithotrity begin. The arrangement of this table resembles that of Table I. and requires no further remark except with regard to the one operation classified as "other." This was a case in which the stone was lodged partly in the bladder and partly in the right ureter. It required for its removal a special operation, which is referred to later. Of the 50 cases here classified, 35 were operated on by lithotrity; of these not a single one died. When it is considered that in 8 of these cases the stone weighed between 2 and 3 ounces, in 10 between 3 and 4, in 8 between 4 and 8, and in one case over 12 ounces, it will, I think, be granted that no other operation has ever yielded such favourable results.[1] The cases have in no ways been picked and none have been refused operation. When I first began to operate I performed suprapubic cystotomy for nearly all large stones. Up to June, 1892, I had operated on 14 such cases, 11 by suprapubic cystotomy with 5 deaths, and 3 by lithotrity, all successful. Of the 36 similar cases operated since then, 32 were treated with lithotrity, 3 by laparotomy, and 1, complicated by stone in the ureter, required a special operation. The last 16 big stones have been removed by lithotrity and all successfully. I consider this result to be such a striking evidence in favour of lithotrity as a treatment for large stones that I have extracted the following small table of lithotrities from the general one.

TABLE III.—*Lithotrities performed for Large Stones.*

		Total.	Age.			Weight in ounces.				
			0–29	30–59	60+	2·3	3·4	4·6	6·8	12
Lithotrity	Urethral ...	15	3	11	1	11	3	—	—	1
	Perineal ...	20	11	8	1	5	7	4	4	—

N.B.—All the 35 cases were cured without fistula.

It will be noted that in the tables above given the lithotrity cases are divided into two classes—urethral lithotrity and perineal lithotrity. By urethral lithotrity I mean Bigelow's operation; that is to say, the crushing of the stone and the removal of all the fragments at one sitting by instruments introduced through the entire urethra. By perineal lithotrity I mean the crushing of the stone by a lithoclast introduced into the bladder through a perineal incision and the removal of all the fragments through the same opening at one sitting. Bigelow's operation was performed in 15 of the 35 cases, and the more experience I have in this operation the more I am convinced that there are very few cases indeed which it cannot cope with. It is true that in the larger portion of the 35 cases I

[1] I have on another occasion (St. Thomas's Hospital Reports, London, 1891) referred to the extraordinary tolerance of Orientals to all operations and diseases connected with the urinary apparatus.

Digitized by Google

have performed the perineal operation. I have done so for one very sufficient reason. The operations are done before students and practically their only experience of stone operations is what they see me do. They will be called upon to operate on large stone cases, and for them and for the great majority of practitioners the perineal operation is by far the better. I therefore take frequent opportunities of demonstrating it to them. In the hands of a surgeon constantly operating, however, Bigelow's operation is practically capable of removing any stone however big. Very large stones have been successfully removed by it. Cunningham[2] records one of eight ounces, but even this has been surpassed by one of my recent cases, which I take the opportunity of recording here. The patient was an Egyptian fellah aged about forty-five years. The stone having been recognised as very big the largest lithotrite, having a gape of 5 inches (made to order for me by Messrs. Down Brothers), was introduced. After some difficulty the stone was grasped, the separation of the blades being to the extent of 4¾ inches. My whole force was necessary to crack the stone, and after a very tiring operation lasting 125 minutes the débris, amounting to 340 grammes, or over 12 ounces (dry weight), was entirely removed. The patient's convalescence was rapid and his cure complete. This is by far the largest stone I have ever crushed, and I believe it to be the biggest ever removed by Bigelow's operation. The stone was composed of urates and phosphates and was more than usually dense.

(To be continued.)

THE BRONCHITIS KETTLE, POULTICES, AND OVER-FEEDING IN ACUTE LUNG AFFECTIONS.

BY F. DE HAVILLAND HALL, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE WESTMINSTER HOSPITAL AND JOINT LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE AT THE WESTMINSTER HOSPITAL MEDICAL SCHOOL.

IN these days of almost exclusive devotion to the study of micro-organisms and of abstruse chemical changes taking place in the body there is some fear lest the attention of the ordinary medical student should not be sufficiently concentrated on what, after all, is to be his main object in life—viz., the cure or alleviation of the maladies from which his patients are suffering. Dr. Church, in his recent Harveian Oration,[1] has pointed out in emphatic language that "the very brilliancy of recent discoveries and the vast increase in our knowledge may for a time react prejudicially on the art of medicine." I frequently hear complaints from the older practitioners with whom I come in contact that recently qualified men fresh from the hospital are almost useless as assistants; their theoretical knowledge may be excellent, but they are at a loss when they are confronted with the small details of general practice. May I, therefore, be allowed a little space in the columns of THE LANCET to discuss the prosaic questions of steam kettles, poultices, and diet? As a text for my sermon let me quote the treatment of a case of pneumonia as it is too often carried out—the unfortunate patient is kept in a room with the atmosphere saturated with moisture from a bronchitis kettle, enveloped in huge linseed meal poultices, and is given nourishment every half hour or so.

First of all as regards the practice of charging the air with moisture from what Sir Benjamin Richardson says is not inaptly called a "bronchitis kettle." The folly of this practice has recently been commented on in a monthly medical journal and attention was therein directed to Richardson's able article on "Hydrops Bronchialis" in the *Medical Press and Circular* of Jan. 25th, 1888. I am strongly of opinion that the bronchitis kettle should be practically banished from the sick room; the only instances in which benefit is likely to ensue from its use are cases of dry bronchitis, in which patients have difficulty in bringing up tough pellets of mucus, and even then I would not order it unless there was a dry easterly wind. In cases of pneumonia I have seen nothing but harm resulting from the employment of the bronchitis kettle, and I always advise that it should be taken away when I find it in use. I do not think that too great stress can be laid on the importance of a free supply of fresh air in cases of pneumonia, and this cannot usually be attained if the bronchitis kettle is at work.

The next point I would raise is as to the routine use of poultices. The longer I practise the fewer poultices I order, and at the present time I have come to the conclusion that except for the relief of pain poultices are of little or no value in the treatment of chest affections, or perhaps I might put it in another way—that the drawbacks inseparable from the use of poultices are not compensated for by the amount of benefit which can reasonably be expected to result from them. To watch a small child with extensive bronchopneumonia fighting for breath, and then to further hamper its efforts by ordering poultices weighing about a pound seems to me hardly a scientific procedure. I prefer a light jacket of Gamgee tissue or cotton-wool over which some stimulating liniment may be sprinkled. This may be left for hours or even days without disturbing the patient, whereas poultices require to be changed every three or four hours and there is always the risk of the patient being chilled by a cold poultice or scalded by one too hot.

Lastly comes the question of feeding. It seems to me that during acute pulmonary affections more food is forced down the patient's throat than he requires and, moreover, that nourishment is given at too frequent intervals. The drawbacks of over-feeding the patient are very forcibly put in a paper read at the International Medical Congress at Berlin by Dr. Andrew Smith of New York. "The anxiety 'to keep up the strength' and the apprehension excited by the small and feeble radial pulse are apt to suggest the administration of more food than is necessary or beneficial. We forget that the digestive organs are not in a condition to do the work demanded of them in health and also that the pulmonary obstruction interferes with the process of hæmatosis. Giving an excess of food therefore entails a double embarrassment. There is the burden arising from undigested food in the stomach giving rise to flatulent distension and thus rendering respiration more difficult, and there is also the risk of loading the blood with more nutritive material than the imperfect respiration can act upon in the process of sanguinification." In all acute affections, unless vomiting be present, nourishment should not, as a rule, be given oftener than every two hours, and about five ounces of milk, or the equivalent, are usually sufficient. I cannot help thinking that the success which attends one's treatment of pneumonia and enteric fever in hospital practice is largely due to the regular administration of a moderate quantity of nourishment.

In the above remarks I have only briefly touched upon some of the important points in the care of the sick, but from my experience in consulting practice I am convinced that too little attention is bestowed on the necessity of laying down clear and precise directions as to the hygiene of the sick room and the diet of the patient.

SOME UNUSUAL CASES OF SWELLING OF THE PAROTID GLAND.[1]

BY RAYMOND JOHNSON, M.B., B.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL AND TO THE VICTORIA HOSPITAL FOR CHILDREN.

I HAVE thought the following group of cases worthy of notice, imperfect as are the records of more than one of them, because they illustrate a minor ailment which appears to have passed almost unnoticed, at any rate in this country. It will be convenient in the first instance to record the brief notes of the cases as they have come under my observation and then to consider their probable nature and refer to cases presumably of the same nature which have been recorded by others.

CASE 1.—A thin, anæmic boy thirteen years of age came to the out-patient department of the Victoria Hospital for Children on Jan. 1st, 1892, on account of a swelling of the right side of his face which had appeared somewhat suddenly

[1] A paper read before the Harveian Society on April 16th, 1896.

Digitized by Google

during a meal a month previously and since then had become somewhat larger and harder. The boy had never had mumps nor was there any evidence that he had recently been exposed to the infection of that disease. On examination it was at once obvious that the swelling was due to enlargement of the right parotid salivary gland. The swelling was slightly lobulated, tender on pressure, in most parts hard, but, especially below the ear, slightly elastic. On squeezing the gland a string of turbid, ropy mucus could be expressed from the orifice of Stensen's duct into the mouth and this was followed by several drops of saliva. A fine probe could easily be passed along the duct, and no calculus or other obstruction could be detected. On the 6th the boy was admitted to the hospital on account of the increasing size of the swelling. It was still found easy to press a long plug of turbid mucus from the duct, after which a free escape of saliva always followed. Hot fomentations were applied externally and hot water mouth-washes were ordered to be repeated frequently. On the 17th the gland was still larger and the swollen socia parotidis was very obvious. The skin over the gland was reddened and the temperature reached 103·6° F. Movements of the lower jaw were very painful, but no increase in the size of the swelling was observed when food was taken. On the 19th the redness and œdema over the gland were so marked that suppuration was suspected. A short incision was therefore made below the ear and a Lister's sinus forceps cautiously pushed into the gland, without, however, finding pus. From this time the swelling slowly diminished, and on the 28th it was noted that the boy was free from pain. On Feb. 2nd the whole gland was still obviously enlarged and remarkably hard. On the 16th it was suggested that iodide of potassium liniment should be rubbed into the gland once daily. When the boy was last examined, on March 22nd, nearly four months after the onset, the gland was smaller but still very hard.

CASE 2.—A healthy-looking boy aged eleven years came to the Great Northern Central Hospital on April 4th, 1892, on account of a swelling of the left side of his face of about one month's duration. The swelling was said to have diminished slightly in size during the last fortnight. It was painful, especially at meals, but it was not stated that the swelling increased at these times. The boy was not known to have been exposed to the contagion of mumps. There was no history of any inflammatory affection of the mouth or throat. On examination the left parotid gland was found to be considerably swollen and tender. The swelling was slightly lobulated, but the socia parotidis could not be defined. Below the salivary gland a few slightly enlarged lymphatic glands could be felt. On pressing the parotid saliva flowed into the mouth from Stensen's duct. Hot water mouth douches were prescribed and belladonna liniment was rubbed into the parotid region. On the 7th pressure on the gland caused an escape of turbid mucus from the duct; the swelling was smaller and softer. A week later, when the boy was last seen, there was still further diminution in the swelling and mucus could no longer be squeezed from the duct.

CASE 3.—A man twenty-six years of age, whilst on a short railway journey in September, 1889, experienced a feeling of discomfort and slight fulness in the left parotid region. On the following day the swelling was much more marked and was exactly limited to the area occupied by the parotid salivary gland. It was very tender on pressure, and mastication was difficult on account of pain. With the taking of food the swelling appeared to increase. Although there was a history of mumps in childhood affecting, it was believed, both parotids, the diagnosis of mumps was made and isolation for a fortnight was strictly observed. At the end of a week the swelling had practically disappeared. During the next three or four years several milder attacks occurred in which the left parotid gland was obviously swollen and slightly tender for periods of a few days. Frequent abortive attacks were noticed in which the socia parotidis alone was swollen and tender for a day or two, and at the present time, six and a half years after the first attack, this part of the gland can still be felt to be slightly enlarged and indurated.

CASE 4.—A thin, ill-tended child aged fifteen months was brought to the Victoria Hospital for Children on Jan. 7th, 1896, on account of a swelling of the left side of the face and neck, which when it was first noticed, five weeks previously, was thought to be mumps. The swelling had gradually increased, but appeared to cause the child no pain. No history of any trouble with the mouth or throat could be obtained. The child, although very ill-nourished, presented no other symptom of inherited syphilis. There was congenital ptosis on the left side. The swelling for which advice was sought was due to uniform enlargement of the left parotid salivary gland, which was sufficiently marked at once to attract attention. The swelling was very hard, but did not appear to be tender. Nothing abnormal could be seen in the position of Stensen's duct. A week later the gland was perhaps slightly smaller.

CASE 5.—A man aged thirty-three years came to University College Hospital on Feb. 19th, 1896, on account of a swelling in the left parotid region. This had gradually been increasing for two months; it was said to be most marked in the morning, but had not been noticed to increase during meals. The swelling had the characteristic outline of the parotid gland, but the socia parotidis could not be separately defined. The swelling was uniformly firm to the touch; it was free from pain and tenderness, but caused some discomfort during eating. The skin over the gland was normal. Pressure failed to squeeze anything from Stensen's duct, and I was unable to pass a fine probe along it. There was no evidence of the presence of a calculus. The mucous membrane of the mouth and throat appeared normal. The patient's general health was not good and for several years he had been under treatment for stricture of the urethra.

In reviewing these short records it will be observed that in each instance we have to deal with swelling of one parotid salivary gland. In none of them was there any difficulty in excluding a swelling due to enlarged lymphatic glands, for although this may sometimes closely resemble a swelling of the parotid itself, in these cases the outline of the enlargement was quite characteristic.

Passing to the consideration of the probable nature of the cases, it may be remarked in the first instance that they were not mumps, although in more than one case the condition had been confused with that affection. Amongst the many reasons which might be adduced in connexion with this point I may mention (1) the absence of any known exposure to the contagion of mumps; (2) the prolonged course of the swelling; (3) the limitation of the swelling to one parotid gland; and (4) the absence of infection of other individuals. Continuing the process of exclusion I may say that in each case the presence of a salivary calculus was duly considered and negatived. In the large majority of cases the essential symptom of a salivary calculus is swelling of the gland due to obstruction of the duct, but there is a specimen in the museum of University College illustrating chronic enlargement and induration of the submaxillary gland resulting from the presence of small calculi in its substance. The gland was excised by Mr. Godlee, who, before proceeding to the operation, believed that he had to deal with a tuberculous lymphatic gland. The course pursued by my cases excluded such a condition. Lastly, there were no grounds in any instance for referring the case to the parotid inflammations which are known as "symptomatic parotitis" or "parotid bubo," such as may occur in the course of pyæmic processes, typhoid fever, &c., or to the group, for our knowledge of which we are so much indebted to Mr. Stephen Paget, in which parotitis complicates various abdominal diseases and injuries, at times apparently independently of sepsis.

Passing from the negative to the positive, I may express my belief that the above cases are examples of swelling of the parotid gland resulting from interference with the escape of its secretion due to inflammation of the lining of Stensen's duct. This conclusion was suggested by the fact that in Cases 1 and 2 pressure on the swollen gland caused the escape of a plug of thick, turbid mucus from the duct, followed by a free flow of saliva. In Case 3 also it will be observed that in each attack the swelling affected first the socia parotidis and in the slighter attacks did not extend beyond it. Remembering that the socia parotidis has a small duct of its own which enters Stensen's duct, it is easy to understand that a slight degree of inflammation, insufficient to block the main duct, might completely obstruct the smaller one.

I have been unable to discover that any particular attention has been drawn to such a condition in this country, but in the article on Diseases of the Salivary Glands in Duplay and Reclus's "Traité de Chirurgie" I have found several interesting references to cases probably belonging to this category. Kussmaul[2] records a case of "recurring salivary tumour resulting from fibrino-purulent inflammation of Stensen's

[2] Berliner Klinische Wochenschrift, 1879, No. 15.

Digitized by Google

duct." The patient, a woman thirty-two years of age, experienced attacks of swelling of the right parotid gland, recurring every five or six months between the summers of 1875 and 1877. The swelling always appeared somewhat suddenly during meals, and was attended with a feeling of discomfort but no actual pain; it lasted for about half an hour and then rapidly subsided. In the summer of 1878 an attack of more considerable swelling occurred, of longer duration and attended with much pain, especially during meals. The swelling subsided after the escape of some drops of thick pus from Stensen's duct. The attacks now recurred more frequently, sometimes after intervals of not more than two or three weeks, and on one occasion the swelling lasted eight days. No treatment beyond the application of dry warmth to the cheek was adopted. Dr. Krieger, who treated the patient, found that the masses which escaped from the duct consisted of pus and fine filamentous cylinders, the fibrinous nature of which was demonstrated microscopically by Dr. Friedländer. The patient was taught to pass a fine platinum wire sound along the duct and thus obtained relief, for on withdrawing it thick fibrino-purulent matter escaped and after this a free flow of saliva. At the beginning of November, 1878, another attack occurred in which not only the right gland, but to a much slighter degree the left, was affected. After the patient's midday meal Kussmaul found great swelling in front of and below the right ear, the skin was red and hot, and pressure was painful. The sound could be passed only a few millimetres along the duct, but on withdrawing it some yellow, creamy pus escaped, followed by a filamentous thread and clear saliva, after which the sound could be introduced for four centimetres. In an attack in January, 1879, the thread which escaped was three centimetres long and as thick as a knitting needle. This was examined by von Recklinghausen, who found that it consisted of a fine membranous deposit composed of a network of fibrin containing pus and epithelial cells. The patient was seen some time subsequently and had had no further attacks. A chlorate of potash lozenge was taken daily. Another case which is worthy of notice was published by Berthold Stiller of Budapest.[3] A man aged thirty-six hurriedly summoned Dr. Stiller on account of a rapidly increasing swelling of the right cheek which appeared during dinner. The swelling corresponded with the right parotid gland and was the seat of a sensation of warmth and discomfort but not of actual pain. Nothing unnatural could be seen in the mouth. Dry heat was applied to the cheek but did no good, for on the following day the swelling was larger and painful. Whilst the patient was handling and squeezing the swelling he spat out a shreddy purulent mass, whereupon the mouth filled with a clear watery fluid. The swelling rapidly diminished and on the following day had disappeared. Subsequently the patient experienced milder attacks every three to six months, and the swelling was invariably relieved by pressure applied to the gland. These two cases afford strong support to the view that I had independently formed as to the nature of at least the first three of those which I have recorded. In both the rapid subsidence of the swelling after relief of the obstruction in the duct shows that it was due simply to retention of secretion and not to inflammation of the gland. In my cases, on the other hand, the persistence of the swelling and induration would point to the occurrence of inflammation of the gland lobules of a kind comparable to that which may occur under similar circumstances in other secreting glands, notably the breast. In Cases 4 and 5 evidence that the primary mischief was in Stensen's duct is wanting, but I strongly suspect that these were also of the same nature.

As perhaps throwing a side light on the subject it may be mentioned that two cases of recurrent swelling of both parotid glands in association with xerostomia or "dry-mouth" have recently been recorded. In Battle's case[4] both parotids had alternately increased and diminished in size for a period of two years, and whilst the patient was under observation and the glands were at their minimum size the smaller was as large as a walnut, and both were firm and lobulated. In Chappell's case[5] the parotid glands "would suddenly enlarge at times, become tender, and after two or three days gradually subside." Whilst the patient was first under observation, in May, 1894, "both parotids were much enlarged, especially the right, and seemingly consisted of three or four nodular masses which were hard and non-sensitive and resembled those of a patient with mumps." In February, 1895, the glands had increased considerably in size. It may be considered probable that in these cases an inflammation of Stensen's duct, associated with the unhealthy condition of the mouth, was the cause of the parotid swellings. A condition similar to that under consideration has been met with in the submaxillary gland by Ipscher.[6] He was hurriedly summoned to a man aged thirty on account of a swelling which had suddenly formed in the right submaxillary region. Before Dr. Ipscher arrived the patient had relieved himself by pressing on the swelling when "a small white thread" appeared in the mouth followed by "a quantity of sour-tasting water." The right submaxillary gland was still considerably swollen, and the corresponding part of the floor of the mouth was reddened. This was the third attack, and in each of the two previous ones pressure on the swelling had been followed by a similar result. This case was published as the result of Kussmaul's communication, and was regarded by Ipscher as of the same nature. The only instance of swelling of the submaxillary gland, possibly belonging to this class of cases, which I have observed was that of a boy eight years of age who was brought to the Victoria Hospital on Feb. 9th, 1894. The swelling in the neck formed during the night in the winter of 1892 and did not subside for eight months. In November, 1893, it reappeared, and when I saw the boy the swelling evidently involved the right submaxillary salivary gland. There was nothing abnormal in the appearance of Wharton's duct, and a probe could easily be passed along it. Three weeks later the gland was smaller. The nature of this case was obviously doubtful.

I have thought these cases worthy of being recorded, although necessarily incomplete in many respects, because they illustrate a condition of some importance, if only on account of its superficial resemblance to mumps. It is a useful rule of practice always to examine the duct of a swollen salivary gland. If there is any probability that the swelling results from blockage of the duct by inflammatory products the regular passage of a fine probe may be expected to give relief, but induration of the gland is likely to persist for a considerable period.

SOME CASES OF VENTROFIXATION OF THE UTERUS.

BY HASTINGS GILFORD, F.R.C.S. ENG.

I VENTURE to bring forward these few cases because the discussion on the subject of ventrofixation of the uterus by the British Gynæcological Society gives them some value from a statistical point of view. But apart from this they are, I think, worthy of publication owing to certain special features of interest. Thus, in one case the operation was done because of the perforation of the uterus by a curette. In another intussusception of the bowel set in after the operation, resulting in self-cure. In two of them both ovaries were also removed. In four Keith's operation was performed.

CASE 1.—A woman aged thirty-five years had severe prolapse of the uterus for five years and had suffered much from enlarged and painful ovaries. No pessary could be tolerated and she became thin, haggard, and utterly dispirited from constant pain and uneasiness. Both ovaries were removed in June, 1893, and the uterus was sewn to the edges of the wound with four silk sutures. It was nearly eighteen months before she had fully recovered her health, but now she is in an excellent condition.

CASE 2.—This patient was a woman aged thirty years. Keith's operation was advised owing to persistent pain in the right ovary and retroflexion of the uterus, but the left ovary being found unhealthy at the time of operation was also removed. This was done on April 18th, 1895, and so far as the displacement is concerned the result is satisfactory, but the ovarian disturbance, though better, has not yet disappeared.

CASE 3.—In November, 1894, I was asked to see a woman

Digitized by Google

aged twenty-six years with a view to the operative treatment of a band which could be felt in the upper part of the vagina, apparently dragging the cervix towards the right and tilting the uterus to the left. The uterus was also displaced backwards and the left ovary was large, prolapsed, and excessively tender. The patient herself was anæmic and depressed by two years of ovarian disturbance which had resisted all treatment. The band was first cautiously divided without influencing the displacement, and then Keith's operation was performed by clamping the left ovary externally. Convalescence was retarded by the appearance of white leg on the left side on the fourteenth day. She is now, however, in good health.

CASE 4.—This patient had suffered from pelvic trouble for six years and had been treated by various gynæcologists without permanent benefit. In the beginning of 1892, when I first saw her, her husband was abroad. Her symptoms were then not of sufficient severity to render an operation necessary, but in the summer of 1894 her husband returned and, her symptoms becoming progressively worse, it was decided that the case should be taken in hand. I found, on examining under ether, that the right ovary was enlarged and so displaced as to bring it under the fundus of the uterus, which was bent down over it. After six weeks' futile treatment by rest in bed, hot-water irrigations, and pessaries I removed the ovary by clamping the pedicle in the wound. She made a speedy recovery and is now quite well.

CASE 5.—In January, 1893, I was consulted by a woman aged twenty-nine years for pelvic pain and metrorrhagia. I found she had an enlarged and retroflexed uterus from which there had been a discharge of blood for five weeks, following amenorrhœa of six weeks' duration. She was given an anæsthetic, and after I had removed the products of conception the uterus was carefully curetted with a blunted "sharp" curette and irrigated with boiled water. It was then noticed that less water came out than flowed in, and a sound was passed which, to my horror, went in up to the handle without a hitch. It was now evident that the fundus of the uterus had been perforated by the curette, and on taking into consideration the size of the aperture, the fact that the discharge from the vagina was offensive, and that some of the contents of the uterus had been washed into the abdominal cavity, it seemed best to perform an abdominal section. The necessary instruments were therefore sent for and prepared while the anæsthetic was continued. On opening the abdomen and inspecting the uterus it was found that an irregularly star-shaped hole had been made through the highest part of the fundus. It was quite closed, and the edges, though ragged, were neither soft nor bruised. After washing out the abdominal cavity with boiled water the fundus of the uterus was sewn to the anterior abdominal wall in such a way that the part adjacent to the perforation was extra-peritoneal. Catgut sutures were used to attach the superficial layer of the uterus to the peritoneum of the abdominal wall, while two silk sutures transfixed the parietes and went deep into the substance of the uterus, one above the aperture and the other below it. A little bloody discharge afterwards oozed from the fundus of the uterus, but in fourteen days the wound had closed and the uterus now remains firmly fixed in place. That which most surprised me in this case was not so much the complete absence at the time of any indications of the mischief I had done with the curette, though I had it well under control, as the lack of that softness or œdema of the uterine wall which one is led to suppose is usually present in these cases. The tissue of the uterus on inspection was seemingly of normal consistency. Moreover, the curette was apparently pushed and not scraped through the uterus, for the perforation was not at the sides where the scraping action of the instrument would come into play, but at the fundus where such an action would have been at a minimum. Writers (e.g., Mr. Lawson Tait[1]) have often called attention to the frequency of this accident, of the impossibility of always avoiding it, and of the rarity with which it is attended with evil results. But under the circumstances I have detailed I think it must be safer to deal with the uterus in the way I have indicated than to leave the matter to chance. The cure of the displacement is also of positive advantage to the patient. I do not think there can be any question that such a course is preferable to that of removal of the uterus, which has been suggested by some continental operators.

CASE 6.—This was of a similar nature to the preceding, except that the symptoms were more severe and the displacement had resisted all treatment. At the time the patient was placed under my care the bleeding had been going on for nearly three months and the discharge was offensive. After curetting the uterus Keith's operation was performed, the right ovary being clamped. On the second day, after the subsidence of the nausea due to the ether, she complained of griping pain across the middle of the abdomen attended with nausea and occasional eructations and vomiting. The pulse was 98. Sulphate of magnesium and enemata of soap and water, of turpentine, and of glycerine (4 oz.) were successively tried without result. Nothing but hot water was now given by the mouth, and after twelve hours the same aperients were tried again with good effect. The pinching pain and nausea and vomiting still continued at increasing intervals for nearly a month after this date, and the bowels acted loosely from two to six times a day. The temperature also went up each evening to 102° F., and dropped to the normal point in the morning. The abdomen became slightly tender and distended, but there were no local signs indicative of pelvic or abdominal mischief. On the fifth day the patient had a shivering attack, when the temperature rose to 102·5°. The uneasiness with which one regarded the continuance of these symptoms was, however, much lessened by the fact that the pulse was of good volume and not rapid, the tongue was moist, and the patient herself looked well and was free from the feeling of illness. On the sixth day the motions became exceedingly offensive. On the fourteenth day the mystery was partly cleared up by the protusion from the anus of a shred of membrane which stank horribly, and proved on inspection to be a piece of the entire thickness of the large intestine, triangular in shape, the base being six inches and the sides five inches long. No other pieces were found. Other symptoms continued, however, with diminishing severity for a month after the operation. Though never before so affected, she now suffered from mixed internal and external hæmorrhoids A rectal examination revealed nothing amiss. The patient is now, six weeks after the operation, steadily improving, and has lost all her symptoms save slight looseness of the bowels. For lack of any better explanation I attribute the complication that ensued in this case to intussusception of the colon from irregular contraction of its walls during or subsequently to etherisation. The case is a good example of the unforeseen accidents that are prone to attend all major operations. It serves to show that no abdominal section can be considered safe however simple the operation.

CASE 7.—This case was similar to Case 3. The patient was twenty-six years old and the results have been excellent.

In none of these instances has the uterus become again displaced. In none of them has there been any trouble with the bladder with the exception of frequent micturition for a few hours after the operation; and even that was present in only two cases. Pregnancy has not followed in any case. I prefer Keith's operation even when there is no ovarian disease because of the mortality which has hitherto attended the performance of immediate suturing of the uterus to the abdominal wall. This mortality I feel sure is far higher than may be inferred from published statistics, for I have myself heard of several fatal cases which have never been made public.

ON THE DISSECTION TO EXPOSE THE LENTICULAR GANGLION.

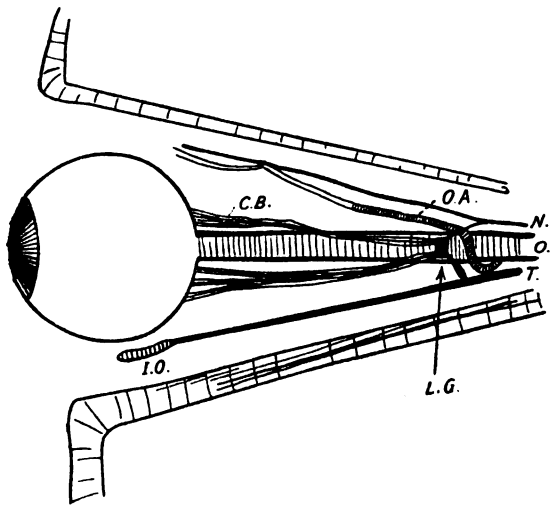
BY EDWARD FAWCETT, M.B. EDIN.,
PROFESSOR OF ANATOMY, UNIVERSITY COLLEGE, BRISTOL.

THIS is a ganglion which is often read about but seldom seen—at all events, satisfactorily. The object of this short communication is to point out how not only the ganglion but its minute branches and roots may always be demonstrated with no difficulty whatever. Most works on practical anatomy recommend the student to dissect the orbit from above. So far as the general contents of the orbital cavity are concerned this method is as economical and satisfactory, perhaps, as any, but it is extremely unsatisfactory so far as exposure of the lenticular ganglion is concerned. Professor

Digitized by Google

Macalister in his "Text-book of Human Anatomy" recommends the dissection of the orbit from the outer side. This method combined with the other gives the most satisfactory view of the orbital contents that can be obtained by the student.

Let us, therefore, suppose that we have removed the outer bony wall of the orbit and have cut through the periosteum of that wall; we will then be struck with the large size of the external rectus muscle which forms a broad covering for the orbital fat which is seen to project below its lower edge. Our duty is now to lift up the external rectus muscle as far as it is possible to do so; we may then raise the fat of the orbit from the lower periosteal wall of the cavity and in doing so we soon expose the inferior rectus muscle. Having exposed this muscle we proceed to make longitudinal cuts through the orbital fat till we expose a thick nerve trunk—that part of the inferior division of the third cranial nerve which goes to the inferior oblique muscle. Having secured this nerve trace it back to its origin, passing the back of the scalpel along its upper aspect; when near the apex of the orbit our progress is arrested by the emergence of a short and thick nerve trunk in length about one-eighth of an inch. This trunk is the motor root of the lenticular ganglion and by following it upwards and forwards the ganglion is found and recognised by its faint reddish appearance. Up to this point the dissection tallies almost exactly with that given by Macalister and is really based on his description. Now comes the essence of the dissection. The ganglion having been exposed, place the head on its side—that side away from the orbit which is being dissected down-



Lenticular ganglion of left side. O, Optic nerve. O A, Ophthalmic artery. N, Nasal nerve. T, Third nerve (branch to inferior oblique). I O, Inferior oblique muscle. L G, Lenticular ganglion. C B, Ciliary branches.

wards; now pour into the dissection some pure spirit and move it backwards and forwards with the end of the handle of the scalpel. In a very short time an almost magical effect is observed, for not only is the ganglion fully displayed, but every branch going to or coming from it is exposed too, and no further dissection with the knife is needed. The ganglion becomes a reality in the minds of students and not what I am afraid it too often is remembered as—something one sees in plates only. It is seen on the outer side of the optic nerve lying with its long axis placed vertically in the concavity of the ophthalmic artery—that concavity formed by the upward and forward bending of the artery on the outer side of the optic nerve. (*Vide* diagram.) The ciliary branches of the ganglion will be seen to pass forward from the antero-superior and inferior angles of the ganglion in two bundles which ultimately resolve themselves into many branches.

ROYAL BRITISH NURSES' ASSOCIATION.—The last sessional lecture of the season will be given on Thursday, April 23rd, at 8 P.M., at the offices of the Association, 17, Old Cavendish-street, W., by Sir James Crichton Browne, M.D. Edin., F.R.S., the subject being "Facial Expression."

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF DEXTROCARDIA.

BY P. N. GERRARD, M.B., B.CH. DUB.

IN January last I was called to see a female aged twenty-six years, well nourished but somewhat anæmic, who was suffering from orthopnœa and was in great bodily distress. She had always enjoyed fair health up to about two and a half years ago, at which time she had an attack of "rheumatism," but had recovered sufficiently to return to her employment. She was a dressmaker and used to carry large bundles of clothes and work the sewing-machine till late at night. Her heart seemed to have first felt the strain upon it about this date (1894), and her condition had gradually but steadily become worse until in February, 1896, the slightest exertion causing extreme dyspnœa and severe palpitation. Of infantile diseases she had had only scarlet fever and measles, both of them so mildly as not to have needed a medical man, and she had never had pleurisy. Her mother had hæmoptysis and three children of the family died in infancy. Her pulse was regular, somewhat more sudden than usual; the ulnar and digital pulse was well marked; the thorax was normal in shape, the breasts were not well developed, but otherwise she was well nourished. Her heart was in an unusual position, as was sufficiently evident from the rhythmical rising and falling of the right nipple. A fairly well marked *frémissement cataire* could be felt over the abnormal apex beat, which was situated on the right side and four and a half inches external to the ensiform cartilage. No impulse was to be felt in the normal position of the apex beat. The superficial area of cardiac dulness extended from the third right interspace downwards and outwards to the apex beat (in the position before mentioned) mingling with the hepatic dulness, and therefrom apparently extending on into the right axilla. At the apex a double murmur was heard, the systolic being transmitted into the right axilla and being well heard at the inferior angle of the right scapula; the point of maximum intensity of the murmurs was at the apex. Proceeding further to examine the conduction of the murmurs they were found to wane as the sternum was approached, their sound being replaced by a single localised presystolic murmur best heard about the junction of the right sixth costal cartilage with the sternum, which I took to be a tricuspid murmur. Over the aortic area a very distinct double murmur was heard in the normal aortic situation, the systolic being conducted along the great vessels with marvellous distinctness outwards as far as the external clavicular origin of the pectoralis major muscle; this murmur was very well marked indeed at the sterno-clavicular articulation. In the normal position of the pulmonary valve a systolic murmur was heard which was quite independent of the aortic systolic murmur and which was conducted on the left over an area of about two and a half inches in diameter round the normal position of the valve in the second left interspace. Hæmaturia was present when the urine was last examined about three weeks previously. The spleen, if enlarged, must be only slightly so, as I have never been able to palpate it below the ribs. The liver was apparently normal in size and position. The menses had always been scanty and pale. During a short period at the beginning of an acute attack of rheumatism, from which the patient is still suffering in some degree, the bases of both lungs were congested, but this had since cleared up, except on the right side, where there still remained some dulness. About the middle of February this year she had a sudden seizure in which, as described to me by her mother, "she sat up in bed and became so breathless and panting that it was thought she would be smothered, and kept groaning in agony with the pain in her side." I suspected embolism of a branch of the pulmonary artery to be the cause. It was very difficult to examine the fundus oculi on account of the excitable condition of the patient, but I believe pulsation of the retinal vessels to be present in a marked degree. As the patient

Digitized by Google

has never had pleurisy or any acute disease, the rheumatism mentioned being of a mild character, I am inclined to believe the case to be of congenital origin.

Tamworth, Staffordshire.

BONNET-PIN IN THE MALE URETHRA.

BY GERARD C. TAYLOR, M.A., B.C. CAMB.,

HOUSE SURGEON, STAFFORD INFIRMARY.

THE accompanying figure accurately shows the length (six inches) of a bonnet-pin I removed from the urethra of a young man last July. Two very similar cases were reported in THE LANCET of 1894.[1] In the present case the patient's account of the accident, though not so ingenious, was at least credible. He stated that a woman with whom he had been spending the evening passed the pin, head first, up his urethra and accidentally allowed it to slip from her grasp. On examination the point of the pin proved to be an inch and a half from the meatus. With a pair of serrated sinus-forceps I succeeded in getting a firm hold on the shaft of the pin close to the point, and extracted it without further difficulty. In both of the cases alluded to above the pointed extremity of the pin, directed towards the external meatus and lying a little distance within it, could not be disengaged from the urethra and was therefore thrust through the tissues as far as the head, after which the operator, having hold of the stem of the pin, was able to reverse its direction in the urethra and to pass it out of the meatus head first. In neither of these cases did the subsequent ill-effects amount to more than a little soreness on micturition lasting only for a day or two.

CASE OF REPEATED CHOLECYSTOTOMY.

BY W. E. TRESSIDER, M.B., B.S. LOND.

THE patient, who was a female, first came under observation in December, 1893, complaining of jaundice, loss of appetite, indigestion, and weakness. She had been ailing at this time for five months, the illness commencing as a bilious attack after which she soon became jaundiced and remained so, the colour gradually increasing in depth until she came under my care. The illness had not been characterised by any severe attacks of pain, but chiefly by a feeling of nausea with indigestion and loss of appetite. After she had been under medical treatment for seven weeks I advised an operation, although no definite swelling could be felt in the region of the liver. The first operation was performed on Feb. 6th, 1894, but nothing definite was found. The gall-bladder was situated very deeply on the under surface of the liver, but nothing could be felt in it, and the abdominal wound was closed up without more than this exploratory procedure being accomplished. The symptoms after this continued much as before until the following June, when the patient had for the first time a violent attack of pain situated chiefly in the back, but also in the pit of the stomach. Her appetite, which before this had improved somewhat, again became very bad and she continued to get worse, having slighter recurrence of the pain, until July 25th, 1894, when, owing to a swelling having become perceptible over the region of the gall-bladder, I advised a second operation which was performed with the result that ninety-two calculi were removed. After this operation she was much better, regaining strength and weight, and for a time did not suffer much from either pain or indigestion, but this improvement was only temporary, for the pain recurred with increased violence, the patient lost strength and weight rapidly, and for a month or six weeks in October and November, 1895, she was in constant pain and almost entirely confined to bed. A third operation was performed on Nov. 30th, 1895, and calculi were again removed—a large one from the dilated common bile duct situated deeply in the abdomen, and eight others. Since this operation the patient has felt well; she has increased three stones in weight, her urine and fæces are now natural in colour, and she can eat ordinary food. This case exemplified a point to which attention has been drawn before—viz., that second and subsequent operations on the abdomen are accompanied by less shock than the first. Although little was done at the first operation the shock was very great, but it was slight at the later operations although the second occupied an hour and a half in its performance and the third more than an hour.

LONDON HOSPITAL.

TWO CASES OF EXTRA-UTERINE GESTATION.

(Under the care of Dr. HERMAN.)

THESE cases form a useful contribution to the subject of ectopic gestation to which attention has been directed by the papers read before the Medical Society at a recent meeting.[1] It is not probable that the condition is becoming more common, but that operation is being more frequently performed in consequence of an earlier and better diagnosis with a more accurate knowledge of the gravity of the condition. The terms idiopathic peritonitis and pelvic hæmatocele are less frequently given as a final opinion of the nature of the patient's suffering; the cause of these affections is sought. The statistics of Formad show the general incidence of ectopic gestation, for in a series of 3500 general necropsies he found it in thirty-five instances. The reasons for operating when the hæmorrhage has taken place outside the peritoneum are suppuration in the hæmatocele, repeated hæmorrhage into the sac, or the continuation of fœtal life. The first of these cases will remind our readers that it is not always necessary to operate through the abdominal wall, as might be imagined from a consideration of the treatment adopted in the cases to which allusion is made above—those read before the Medical Society.

CASE 1. *Tubal pregnancy leading to tubal mole and intra-peritoneal hæmatocele; incision by the vagina; removal of tubal mole; recovery without bad symptoms.*—A woman aged twenty-eight years was sent to the London Hospital by Dr. Bate of Bethnal-green and admitted on Feb. 9th, 1896. She began to menstruate at thirteen years of age and had always been regular, the flow being scanty and painless. She had

[1] THE LANCET, March 28th, 1896.

Digitized by Google

had four children and no miscarriages. Her last child was born on Nov. 5th, 1894. She nursed the infant until December, 1895. Her first menstruation after the confinement was in October, 1895. Her last menstruation ceased on Jan. 13th, 1896. Soon after the last-mentioned date she took a hot bath and thought that she then caught cold. Ever since she had had bleeding from the vagina and pain in the lower abdomen. The bleeding was continuous every day, but not great in quantity. When admitted the patient was found to be well nourished but slightly anæmic. On abdominal examination a swelling was felt rising out of the pelvis two and a half inches above the pubes. By the vagina the uterus was found so pushed forwards and upwards that it formed the most prominent part of the abdominal swelling. Behind it was a convex, tense swelling bulging down Douglas's pouch. On Feb. 29th the swelling was larger. On abdominal palpation it was felt to reach to within three fingers' breadth of the umbilicus. By the vagina the uterus was found still further displaced forwards and upwards and the swelling behind it was as big as a fœtal head. By the rectum the swelling was felt to be altogether in front of it, not surrounding it laterally. There was no fever. The fixity of the swelling and the displacement of the uterus made it clear that the effusion was under pressure, not free in the peritoneal cavity. The absence of fever and the presence of anæmia and of slight uterine hæmorrhage made it probable that the effusion was blood. As it was increasing it seemed that the cause of the bleeding was still active, and that therefore interference was indicated. On March 3rd an incision big enough to admit four fingers was made in the posterior vaginal cul-de-sac. Fluid blood and clots came away. With the fingers the cavity was thoroughly emptied and examined. It had a firm concave roof. On the right side and behind a mass was found lodged in a cavity bounded by a fringed wall which projected into the main cavity. This was detached and removed. The fringed wall was plainly the open end of the Fallopian tube. The cavity, after being emptied, was loosely packed with iodoform gauze. The solid mass removed measured two inches by one inch and a half. It appeared to consist mainly of clotted blood, but at one part was a reddish-white solid lump about the size of the kernel of a nut, from which processes seemed to go out into the clot. This was afterwards examined microscopically and found to consist mainly of fibrin, among which were unmistakable chorionic villi. On the 6th the gauze was removed. The cavity was afterwards daily washed out with a saturated solution of boric acid. There was no fever. Small clots occasionally came away, but there was no considerable hæmorrhage. On the 24th the uterus was freely movable. The cavity behind it measured only an inch and a half in length. The patient went out well on April 10th.

CASE 2. *Tubal gestation; early death of the fœtus; subsequent hæmorrhage into closed Fallopian tube; removal; recovery.*—The patient, a strong, healthy-looking woman aged twenty-one years, gave the following history. She had been married two years and had had one child, born in May, 1894. She made a good recovery and nursed the baby. She menstruated for the first time after the birth of the child on March 27th, 1895. Excepting during childbed she had never been laid up, and since the delivery she had been well except for a little discharge of "whites." On April 26th, 1895, she was suddenly seized with pain in the left side of the lower abdomen. She fainted, and on recovering consciousness vomited, and there was a little bleeding from the uterus. With rest in bed the pain and bleeding gradually diminished, but four days afterwards it recurred as severely as before and the bleeding also returned. The symptoms gradually got better and she resumed her household duties. On May 12th the pain and bleeding again returned, and on May 18th she came to the London Hospital and was admitted. She had weaned the child shortly before admission. On abdominal examination there was some increased resistance low down on the left side. Examination by the vagina showed that slight hæmorrhage from the uterus was going on. The uterus was displaced slightly forwards and to the right by a swelling behind and to the left of it. The swelling felt elastic; its lower outline was convex; its upper limit did not reach higher than the fundus uteri; it was tender on pressure. Examination by the rectum revealed that the swelling did not surround the bowel, but reached to the pelvic wall on the left side. On June 9th the physical signs were much the same. The swelling was not larger. Since admission the patient had had two attacks of pain, each accompanied by increased bleeding from the uterus. For private family reasons the patient left the hospital. The patient returned to the hospital on June 18th. Since leaving it she had had several attacks of pain, accompanied by fainting and much more bleeding. On examination a rounded swelling was felt in the left lower abdomen. By bimanual examination it was found that the swelling in the left posterior quarter of the pelvis had increased to the size of a fœtal head. Operative treatment was therefore advised. On opening the abdomen the tumour was found to be the left Fallopian tube distended with blood clot. It was removed. The patient made a good recovery. The clot in the tube was carefully examined, but no trace of a fœtus could be found in it. Microscopic examination of sections of the wall of the tube showed unmistakable chorionic villi.

Remarks by Dr. HERMAN.—In Case 1 the increase in size of the swelling, indicating fresh hæmorrhage, pointed out the necessity of interference to remove its cause. There were two ways of doing this—by the abdomen or by the vagina. By abdominal section the general peritoneal cavity would be opened and the patient left with a scar in the abdominal wall, but the parts could be seen and treated with greater precision. This last consideration would make abdominal section better treatment than tapping by the vagina or making a small incision simply to let out the blood. In favour of approaching the disease by the vagina were the great bulging of Douglas's pouch and displacement of the uterus, which showed that the collection of fluid was quite shut off from the peritoneal cavity; hence this need not be opened and there would be no scar. By making a free opening, inserting the hand, and carefully examining the wall of the cavity, not only the blood was liberated, but the cause of the bleeding (the tubal mole) was found and removed. In similar cases I think this the best practice to follow. These two cases are instructive as illustrating a clinical fact—viz., that when the ovum in a tubal pregnancy has died, and the pregnancy as pregnancy has ceased to advance, the patient is not on that account free from danger; it cannot be said that the morbid condition is one which is innocuous and certain to get well if let alone. In both these cases considerable bleeding took place although the embryo must long have been dead.

KASHMIR MISSION HOSPITAL.

TWO CASES OF LAMINECTOMY FOR POTT'S DISEASE; REMARKS.

(Under the care of Mr. ARTHUR NEVE.)

MR. NEVE refers in his remarks to some of the principal reasons for performing the operation of laminectomy in cases of paraplegia due to spinal caries. We agree with him in the opinion that it is an operation which is rarely required, although from his statement it appears he has found it necessary in 10 per cent. of all cases seen at the Kashmir Hospital. As a rule we should operate only in grave cases in which acute compression, the appearance of respiratory or urinary complications, and the rapid development of degenerative processes force us to interfere, or in which the course of a chronic case is steadily toward a fatal termination although no advanced visceral tuberculous lesions are present. The opening of the spinal canal and the necessary manipulation of the cord has caused at times very severe shock, so that the idea of operating in such a manner as to get at the focus of disease without opening the spinal canal has been suggested to more than one surgeon. A procedure very similar to that which Mr. Neve has tried is credited to Dr. Ménard of Berck-sur-Mer. That surgeon makes a vertical incision at the point of greatest deformity through skin and muscles. One or two transverse processes are resected with gouge-forceps, also the posterior extremities of the corresponding ribs (subperiosteally). The periosteal canal of the removed ribs is followed with a curved director, the tuberculous focus in the vertebral bodies entered, and the diseased material cleared away. A double drain is then inserted and the cavity washed out with antiseptic lotion. He has had a certain amount of success with this method.

CASE 1.—A girl aged eighteen years was admitted to hospital with a prominent dorsal curvature and paraplegia of six months' duration. Both legs were much wasted and there was no voluntary movement, but in the left leg

Digitized by Google

exaggerated reflexes and ankle-clonus were present. In both legs she experienced morbid sensations as of ice or fire and needle pains, but there was no ordinary sensation. Her general condition was good. On Sept. 18th, 1888, the operation of laminectomy was performed on the eighth and ninth dorsal vertebræ. There was no trouble from bleeding; a saw was used for removing the bone. The membranes of the cord looked healthy and pulsated freely. The wound was closed and healed firmly within a fortnight. At first she complained a good deal of increased pain, and on the third day it was noted that she could move her left leg, but any hope of improvement soon died away; and when she was discharged from hospital a month after the operation the lower limbs were in the same paralytic state.

CASE 2.—A boy aged seven years had been paraplegic for only two months, though the curvature was of two years duration. The paralysis was very complete, being sensory as well as motor. Extension with weights and pulleys was applied to the head and the feet. After six weeks' treatment it was noted that "he seems to localise better when touched, also moves toes and draws up knees, but cannot straighten them." No further improvement took place till after operating. On June 21st, 1895, laminectomy was performed. The spines of the fifth and sixth vertebræ were severed with bone pliers, and then the corresponding laminæ. The dura mater looked healthy and the cord pulsated. At this moment the respiration seemed very embarrassed and it became necessary to turn the patient on to his back. The sensation in doing so was as if the upper and lower parts of the trunk were quite disunited, one of awful flaccidity. In a minute or two the pulse and respiration improved and the operation was resumed in a semi-prone posture. A drop or two of curdy pus was seen oozing from in front of the cord. This was syringed away, a little iodoform dusted in, and the muscular and skin layers carefully apposed with catgut sutures, not leaving any aperture for drainage. The wound was not seen till July 3rd, when it was found healed under the original dressing. Already sensation and power were returning. Ten days later the wound reopened and a little over one ounce of pus was discharged. He was taken away to his own village on Aug. 7th; at that time there was still some discharge from the sinus. In December he came to the hospital again and walked unassisted into the consulting-room. Both sensation and power had returned, but he was still in an emaciated condition.

Remarks by Mr. NEVE.—Operative interference in cases of Pott's disease has been rare in the past and will probably be no more frequent in the future. Except in those instances in which abscesses have to be dealt with, operations can only be indicated when the function of the spinal cord is affected by pressure—in other words, when there is paraplegia. The occurrence of paralysis in Pott's disease is variously estimated at from 8 to 30 per cent. But Mr. Muirhead Little[1] states that in over 75 per cent. of such cases the patients recovered power over their limbs under treatment by rest and extension. As some of those cured were paraplegic for months, it is evident that hasty operation is to be deprecated. There is a residuum of from 2 to 5 per cent. of cases in which the patients are hopeless without operation; but many of them are unsuitable for any severe operative measures owing to extreme debility, general tuberculosis, or other complications. So the scope for laminectomy is but small. Spinal caries is far from common in Kashmir. The hospital serves a population of over a million, but probably less than twenty cases of Pott's disease have been seen in the last ten years. Of these, four cases have been operated on—two on account of paraplegia and two in which abscesses had burst in the dorsal region. It is the former which are now in question. When Macewen[2] published his splendid series of laminectomy cases it seemed as if the usual cause of paralysis in Pott's disease was the presence of a connective tissue tumour (hypertrophic pachymeningitis) pressing upon the cord. A similar case was also published by Mr. Wright,[3] but such has not been the experience of Mr. Arbuthnot Lane,[4] who has usually found direct pressure by an abscess on the cord or occasionally bony narrowing of the canal. Nor in the two cases recorded above was there any noteworthy thickening of the spinal meninges. In the paraplegia of Pott's disease diagnosis does not keep pace with the possibility of treatment. In any given case the surgeon wants to know what is the pressure-producing condition. If it is recent (as in Case 2) and due to bony narrowing or to thickening of, or deposit on, the membranes laminectomy may be necessary as well as beneficial, but it must be remembered that it weakens the spinal column. It has been proposed in Pott's disease to wire the spines of the vertebræ together. This is a comment upon laminectomy. It is noteworthy that in the above cases, as in others which have been recorded, improvement was connected with the evacuation of purulent matter. Such abscesses are usually anterior to the cord. It might be well in operating, after exposing the posterior surface of the laminæ, to pass a trocar forward between the transverse processes and explore both sides of the body for pus, which is present in a large percentage of cases. If found, the surgeon would then leave the posterior portion of the vertebræ uninjured and would direct his efforts to the anterior disease. In two cases of dorsal caries unaccompanied by paralysis I have endeavoured thus to attack the seat of disease. In both there were sinuses leading inside the thorax. The first case occurred in 1882 and the second in 1888. They were almost identical. In both the transverse processes of two vertebræ and portions of ribs were removed and the side of the bodies of the vertebræ gouged. In the first case the patient, when apparently convalescent, died quite suddenly from an unknown cause, possibly the bursting of an abscess inwardly. The other patient made a good recovery. All the above harmonise with the published accounts of other cases. They show that operation is not devoid of risk and often fails to afford relief; but with careful selection of cases and, of course, thorough asepsis the risk is worth running for the sake of benefiting one here and another there whose condition is otherwise hopeless, and with further experience better results may be expected.

[1] THE LANCET, July 23rd, 1892.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Note on the Endemic Fever of the Mediterranean.

AN ordinary meeting of this society was held on April 14th, the President, Dr. DICKINSON, being in the chair.

Surgeon-Captain M. LOUIS HUGHES communicated a note on the Endemic Fever of the Mediterranean. He said that no suitable name had yet been suggested for this specific form of fever, nor was there any heading in the official nomenclature of diseases under which it could be returned. For the purposes of the paper it was termed "Mediterranean fever." It was endemic in various parts of the Mediterranean, and possibly in the Red Sea and elsewhere, while it also occasionally occurred in the form of localised epidemics. Though it appeared to have existed in Malta and Gibraltar since the beginning of the present century it was first accurately described by Dr. Marston in 1861 and had only found a place in English text-books during the last three years. Clinically this fever had a peculiarly irregular temperature curve, consisting of intermittent waves of pyrexia of a distinctly remittent type. These waves of pyrexial intensity were separated by periods of apyrexia or abatement of severity, giving a peculiar relapsing character to the fever. In some instances the daily remissions became so marked that the temperature might become intermittent (but non-paroxysmal) in character. Its duration was long and indefinite, the average pyrexial duration being from sixty to seventy days, the average stay in hospital over ninety days, while cases had been known to suffer from the pyrexial condition for over six months. This pyrexia was accompanied by progressive anæmia, a tendency to constipation, swelling and effusion in various joints, profuse perspirations, and a peculiar irritability of the nervous system characterised by sciatica and other neuritic symptoms. Pathologically the spleen was enlarged and softened, many of the organs were congested, but the intestines were free from ulceration. The microscopical appearances were those of toxic irritation of the tissues. A definite species of micro-organism (discovered by Bruce in 1886) was constantly present in those tissues where from clinical symptoms and post-mortem appearances it might be expected to be present.

Digitized by Google

Pure cultures of the "micrococcus militensis" produced by inoculation into the tissues of monkeys a similar form of pyrexia and in all other points fulfilled the postulates laid down by Koch. The disease prevailed during the hot dry months between May and October, with a maximum prevalence in July, August, and September. It was not contagious, nor did there appear to be any close connexion between its prevalence and the milk, water, or food supplies. Its dissemination appeared to be brought about on shore by an aerial infection arising from drains or soil infected by the excrement of previous sufferers from the disease. By this means it entered the human system by way of the throat or air-passages. Its prevalence followed an inverse ratio to the amount and continuance of the rainfall. The mortality did not exceed 2 per cent. of cases, but the duration of sickness was very long. No specific drug at present in use would cut short the disease. Successful treatment consisted in aiding nature by careful nursing and dietary, by confinement to bed during the acute stages, by such symptomatic treatment as might be required, by removal from all sources of reinfection, and last, but by no means least, by a moderate regulation of temperature by the external application of cold, whereby fatal results were averted and severe cases converted into mild ones.

Dr. THIN said that when in Malta last autumn he endeavoured to find out if this disease was connected with malarial fever. He carefully examined the blood of six patients in different stages of Mediterranean fever to see if the parasite of malaria could be found in the blood. He could discover neither parasites nor pigment in the blood or the spleens of those whom he examined. Typhoid symptoms were characterised by their absence, and the intestinal lesions were not of typhoid nature. One characteristic of the disease seemed to be that the patients were quite unaware of the gravity of their condition. Professor Pisani of Malta had told him that whereas formerly the fever was confined to those parts of Malta where English soldiers or sailors were commonly present it was now common in the country districts. In the neighbouring island of Gozo the fever was formerly absent and patients were sent to convalesce there, but now the fever had taken root there as well. The fever was the most serious disease connected with Malta, and it was of the utmost importance to the Government to devise means to check its ravages. It occurred probably in other parts of the world, such as Hong-Kong, where a fever of the same type as that described had recently reappeared. In Sicily the disease was formerly not known, but there was an epidemic in 1872. For some years afterwards a few sporadic cases occurred; then in 1884 an epidemic broke out at Catania and also in country districts where the air and sanitary conditions were beyond suspicion. Cases also occurred on the sides of Etna. It was a fever with an absence of symptoms that were specific or pathognomonic, and in most instances there was excessive sweating. At the apex of the lung a condition was often present which suggested phthisis but was not so. He held that the Government should take steps to have the fever fully investigated.

Dr. NORMAN MOORE said that Dr. George Cleghorn, in a book on the "Diseases of Minorca," described an affection which was clearly Mediterranean fever, and which was existent in Minorca between 1740 and 1751, at the time when the island was occupied by our troops. Dr. Cleghorn was of course prejudiced with the old classification of fevers and he regarded this as a variety of tertian, but his descriptions were very clear and he recorded 100 post-mortem examinations. He mentioned that definite destructive ulceration of the mucous membrane of the large intestine sometimes occurred; that certain varieties of skin rash appeared in the course of the affection; and that it was often complicated with pleurisy, and doubtless under this term he included croupous pneumonia also.

Dr. PATRICK MANSON said that he had had but little experience of this affection. He had seen several cases in London and one or two in China. In Hong-Kong he had seen a patient suffering from what he now thought must have been Mediterranean fever. In Amoy he once witnessed an epidemic of a fever in which there were two pyrexial waves separated by an apyrexial interval. As our knowledge became more accurate a great variety of fevers would no doubt be found to exist. From what was known of the affection under discussion it certainly was not malarial and not typhoid. Every credit was due to Surgeon-Captains Bruce and Hughes for the work they had done on the subject.

MEDICAL SOCIETY OF LONDON.

Osteitis Deformans.—Tumour of Liver associated with Jaundice.—Lymphatic Obstruction of Lower Extremity.—Congenital Angeioma of Neck.—Lateral Spinal Meningocele.—Spontaneous Dislocation of Patella.—Hairy Mole of Face—Sarcoma of Rectus Abdominis.—Cervical Rib.—Carcinoma of Larynx.

An ordinary meeting of this Society, for the exhibition of clinical cases, was held on April 13th, the President, Sir JAMES CRICHTON BROWNE, being in the chair.

Dr. DE HAVILLAND HALL exhibited a man aged forty-eight, who was the subject of Osteitis Deformans. The left leg had been noticed to be getting larger for seven years and the head for two years. The enlargement of the head was more on the right side and the maximum circumference was 25¼ inches. The lower jaw was slightly thickened but the face was not otherwise involved. The left tibia and femur were especially thickened, the right to a less degree. There was also angular curvature in the lower dorsal vertebræ. He had suffered from much pain which he referred to the bones and it was noteworthy that this had been quite relieved by the administration of quinine with iodide of potassium.—Dr. de Havilland Hall then showed a case of Tumour of the Liver associated with Jaundice. The patient was a man aged thirty-one, whose illness commenced with vomiting, pain in the abdomen, diarrhœa with clay coloured stools, bile in the urine and irritable skin. The liver dulness extended below the umbilicus and the organ was painless on palpation. He remained in the hospital nearly three months and on his discharge was still jaundiced. Dr. Hall regarded the case as one of hydatid cyst and looked upon the jaundice as catarrhal in character, spreading up from the duodenum into the common duct.—Dr. de Havilland Hall likewise showed a case of Lymphatic Obstruction of the Left Lower Extremity. The patient was a female aged twenty-five who had suffered from a swelling of the foot for four years. There had been no pain. The swelling extended up the leg to the thigh. The patient had never lived out of England. On admission there was a bluish discolouration of the leg, which disappeared on the adoption of the recumbent position. The leg was kept at rest, was bandaged, and iodide of iron with iodide of potassium administered. The leg was enormously swollen, did not pit on pressure, and the condition appeared to be allied to elephantiasis.—Mr. CLUTTON asked if there had been vesiculation. All the cases he had seen had presented a warty condition about the malleoli, and there were dilated lymphatic vessels which discharged a clear fluid. The cause of the lymphatic obstruction was difficult to find. If they occurred in young people the limb generally became elongated.—Mr. WATERHOUSE said that he had had had a precisely similar case under his own observation. The patient was a Jewish girl aged eighteen. The left leg was involved and no cause could be found, even after careful pelvic examination under an anæsthetic. On puncture of the limb ordinary lymph escaped. Martin's bandage was applied and this had produced a steady and continuous diminution of the circumference of the limb, which was one inch longer than its fellow.—Mr. G. R. TURNER asked if chyluria were present.—Dr. DE HAVILLAND HALL, in reply, said that the urine was normal and there had been no escape of lymph from the leg.

Dr. E. CAUTLEY showed a case of Congenital Distensile Tumour of the Neck. The patient was an infant aged five and a half months, who presented a swelling on the left side of the neck which became visible when the child cried. It lay behind the sterno-mastoid, but passed under that muscle. It was non-pulsatile and dull on percussion. He regarded it as a large venous angeioma.—Mr. BATTLE asked if there were any dulness in the upper part of the chest and whether the swelling had been tested with transmitted light.—Dr. CAUTLEY, in reply, said that the swelling was not translucent and that there was no chest dulness.

Mr. BATTLE exhibited a case of Lateral Spinal Meningocele. The patient was an ill-developed infant aged two and a half months who presented a congenital fluid swelling of the size of a goose's egg to the left of the upper part of the sacrum; the swelling presented alterations of tenseness when the child cried and it could be partly reduced on pressure, but the skin covering it was quite normal. A distinct deficiency could be felt between the posterior superior spine and the spine of the sacrum, and the poster. r

Digitized by Google

superior spine was further away from the middle line than normal, being evidently displaced outwards.—Mr. Battle next showed the result of operation in a case of Spontaneous Dislocation of the Patella. The patient, a girl, was admitted to hospital in December last complaining of inability to walk far and a tendency to fall at times. The patella was found to have become dislocated on to the outer condyle of the femur, and on flexion to a right angle it slipped completely out of the intercondyloid groove. The quadriceps extensor was wasted, and this wasting was more marked on the inner side of the thigh. The external condyle was apparently ill-developed. Improvement followed osteotomy after Macewen's plan, but there was still a tendency to displacement outwards when the limb was fully flexed. This might probably be overcome by the use of special apparatus.

Mr. CLINTON DENT showed a case of Hairy Mole of the Face. The patient was a boy aged twelve, and the mole had been treated by repeated shaving of the cutis to get beneath the pigmentary layer. This shaving had produced a nævoid condition, and probably it would have been better to have excised the mole and applied skin grafts. It was remarkable that under the repeated shaving the hairs had become nearly white.—Mr. Dent also showed a woman, twenty-three years of age, with a Sarcoma of the Rectus Abdominis Muscle. The tumour appeared to be situated within the sheath of the rectus and was said to have at first diminished under the use of iodide of potassium. But it had increased markedly during the last fortnight, and other nodules could now be felt in its neighbourhood.

Mr. G. R. TURNER showed a case of Tumour of the Neck. The patient was a girl aged sixteen, who had only noticed the swelling of the neck for the last nine months; it had increased but slightly in size since November last. The swelling gave no trouble, except for numbness down the left arm. There was occasional grating on moving the scapula over the tumour. The mother had a bony swelling on the right side of her neck. They were both considered to be instances of cervical rib.—Mr. DENT doubted this diagnosis. He thought that there was a deformity of the ribs themselves, and a consequent displacement of the scapula.

Dr. GILBART SMITH showed as a card specimen a Larynx Affected with Epithelioma. It was removed from a man aged fifty-eight, who had suffered from his throat for six months. On examination it was found that the epiglottis was swollen and curled back; there was swelling of the right aryteno-epiglottic fold, and the space between the vocal cords was blocked by two or three excrescences springing from the base of the epiglottis. It would be thought that with such a condition the patient would have urgent dyspnœa, but as a matter of fact he did not suffer from dyspnœa till the day before his death. He died from heart failure a few hours after tracheotomy was performed. On examination the epithelioma appeared to have commenced in the neighbourhood of the epiglottis and then to have spread towards the right arytenoid cartilage.—Dr. DE HAVILLAND HALL said that if an obstruction were only gradually increased it could be borne without dyspnœa until the space for air entry was extremely small. He had recently seen a case which illustrated this fact.

CLINICAL SOCIETY OF LONDON.

Two Cases of Acute Abscess of the Liver.—Albuminous or Serous Expectoration after Paracentesis for Serous Effusion.—Sarcomatous Cranial Cyst.—Sequel to Case of Syphilitic Cranial Necrosis.

AN ordinary meeting of this society was held on April 10th, the President, Dr. BUZZARD, being in the chair.

Mr. R. J. GODLEE read the notes of two cases of Acute Abscess of the Liver. The first was one of pyle-phlebitis in a man aged forty-one years, who had an acute illness in June, 1895, which left him with pain in the region of the liver, for which he was seen in September. He had a hectic temperature and one rigor. There was obvious swelling of the liver. A drainage-tube was inserted. There was slight improvement for a day or two, which was not maintained. Post mortem there was old inflammation about the cæcum, clotting of the right branch of the portal vein, and the corresponding part of the liver was riddled with abscesses. The left portal vein was patent, and the left lobe of the liver was free from suppuration; the patient had also purulent meningitis. Remarks were made on the pathology and treatment of this condition. The second case was that of a previously healthy man aged fifty-eight. The disease began insidiously a month before he came under notice; there was very rapid enlargement of the liver accompanied by rigors. An abscess was found upon the under surface of the liver, containing about one pint and a half of stinking pus. The patient was very feeble before the operation and died of shock.—Mr. ARBUTHNOT LANE said that he remembered seeing a patient who was at first thought to be suffering from biliary colic, but the temperature rose to 103° F., and the gall-bladder became very distended and tender. On palpation he recognised that gall-stones were present, so he removed them in the usual way. The gall-bladder was adherent to all the surrounding structures, including the large intestine; he, therefore, made no attempt at exploration in its neighbourhood, but the gall-bladder was stitched to the skin and a tube left in. There was no jaundice. Two days later she had an attack of her old pain; the temperature was then normal, but it speedily rose as high as 107°, and the patient died seven hours later. At the post-mortem examination a large abscess was found behind the portal vein, and it was believed that this abscess had burst either into the main vein or into one of its branches.—Mr. SPURRELL asked why, in fixing the liver to the surface, Mr. Godlee had passed his sutures only half an inch into the organ.—Mr. GODLEE, in reply, said that the sutures were passed superficially because he believed that the pus was near the surface.

Dr. SAMUEL WEST read a paper on Albuminous or Serous Expectoration after Paracentesis for Serous Effusion. He said that it sometimes happened that during the paracentesis the patient began to cough and complain of some shortness of breath and soon after to expectorate a quantity of clear, frothy fluid. The cough was almost constant, though not very violent or paroxysmal, and with it there was some shortness of breath and, occasionally, also even considerable dyspnœa. Wheezing and crepitation were heard over the lung, usually over the affected side only, but occasionally on both sides. After the symptoms had lasted for an hour or two, or perhaps a little longer, they usually subsided and the case ran its ordinary course, but every now and then the symptoms were extremely severe and the patient died of suffocation. Albuminous expectoration was really very rare—one of the rarest events in pleuritic effusion. He related the case of a man aged about forty, who had a right-sided effusion for about three or four weeks. He performed paracentesis himself, using the syphon and not the aspirator. The fluid flowed readily, and after about forty ounces had been withdrawn the patient began to cough. The cough increased in frequency and caused much distress. This was soon followed by a little dyspnœa. Expectoration commenced in about ten minutes, and in an hour the patient brought up about eight ounces. The attack lasted for three hours, during which a pint of frothy fluid in all was coughed up. Over the right side (the side of effusion) there was a good deal of wheezing and crepitation, and a little also on the left. The patient's condition was in no wise such as to cause alarm, the symptoms rapidly subsided, and the patient made a good recovery. The cases of albuminous expectoration differed a good deal *inter se*. The attacks usually came on during paracentesis or immediately after it, sometimes as long as two hours. They lasted for a short time, usually not more than an hour or two, but occasionally longer. The quantity of fluid varied from a few ounces to even more than three pints. In character it was frothy, like that of acute bronchitis. It contained much mucin and little albumin. The physical signs were those of congestion of the lungs. There appeared to be no necessary relation between the duration of the pleurisy prior to paracentesis and the liability to serous expectoration, but, as a rule, the cases had lasted some little time. It was not to be connected with the use of the aspirator, for some of the cases, as in the present, occurred when the fluid was removed by the syphon only. The result was rarely fatal, and among the fatal cases some complication besides the effusion was generally found. The condition seemed less common than it used to be twenty or thirty years ago, probably because of the earlier performance of paracentesis. There were three explanations given of the phenomenon: 1. Perforation of the lung during paracentesis and the discharge of the pleural effusion through the lung; but the difference of the chemical characters of the two fluids showed that this explanation could not be correct. 2. The absorption of effusion by the lung. 3. Œdema of the lung; and this was the only

Digitized by Google

satisfactory theory. In the non-fatal cases this œdema must be due to some transitory condition and was probably in most cases to be connected with the sudden distension of the lung after it had been collapsed for some time. In the fatal cases some organic lesion was generally found in addition which would account for the result. In some of them the lesion was such as would cause obstruction either of the vessels of the lung or of the bronchial tubes and possibly also of the lymphatics; in others there was disease of the opposite lung—e.g., general pleural adhesion or morbus cordis. The subject had been brought before the society with the object of eliciting the experience of others, especially as to its frequency, which appeared to be very much less than it was commonly stated to be, for the present instance was the only one which had come under Dr. West's observation out of a very large number of cases of pleural effusion.—Dr. DE HAVILLAND HALL said that when collecting materials for a paper on pleurisy some years ago a search into the literature showed that the only cases then recorded were foreign. The only case he had since met with was reported from the Canterbury Hospital in December last. These cases were not only exceedingly rare, but also of considerable gravity. He agreed that the condition was probably due to œdema of the lung, and for treatment he would try dry-cupping followed by sinapisms to the chest, while internally he would recommend nitrite of amyl or nitro-glycerine.—Dr. HALE WHITE referred to the case of a patient who was recently admitted into Guy's Hospital suffering from pleurisy with effusion. For four or five days after aspiration she expectorated albuminous fluid in considerable quantities. After the first aspiration the temperature began to rise and a second collection of fluid was forming which might necessitate a second aspiration.—Dr. F. L. BENHAM said that he could not understand why, if this phenomenon were due to pulmonary œdema, it was not met with in œdema from ordinary causes. He thought it more probable that there was thrombosis of the pulmonary vessels.—Dr. WEST, in reply, said that pulmonary thrombosis had been commonly observed in the recorded instances of this disease, and he agreed that this was a very probable explanation. It was rare for the expectoration to go on for more than forty-eight hours. In the minor cases no active treatment was required, while in the acuter forms there was not time to carry out treatment.

Dr. NEWTON PITT and Mr. ARBUTHNOT LANE gave the details of a case of Cranial Cyst of Sarcomatous Origin. The patient in 1891 first complained of pain on the top of his head where he found a soft area. He paid little attention to this condition till September, 1893, when it bulged outwards, forming a tumour as large as an egg. This swelling gradually subsided. On four occasions it became enlarged and painful, subsiding by the discharge of a considerable quantity of serum through an orifice which formed in the scalp. He was first seen in November, 1892, when the swelling measured about two and a half by two inches. It fluctuated and also pulsated distinctly. A few days after its contents discharged themselves, about an ounce being collected and examined, when it was found to be simply serous. A depression three-quarters of an inch deep replaced the swelling and was bounded by a thin, irregular bony margin, which in parts yielded slightly to pressure. In December, 1892, the scalp over this area was freely divided, when a space was exposed which extended some little way beneath the overlapping edge of bone. Covering the whole of the floor, being most abundant at its limits and destroying the overlapping bone, was a quantity of some material which was apparently sarcomatous in structure. This structure was verified by subsequent examination. As the growth was so soft and extensive it was not felt advisable to remove such a large area of bone and dura mater as would be required for its entire elimination, so the wound was closed. Since the operation, except for a temporary leakage of serum and for a subsequent attack of erysipelas, the patient has enjoyed excellent health and has had no return of the headache from which he suffered previously to the operation.—Mr. MAKINS said that he recollected a case which resembled that under discussion. A patient presented himself at hospital with a large tumour of the upper jaw of less than a year's growth and attended by severe hæmorrhage. There was a distinct history of syphilis, but the tumour did not present the usual characters of a gumma. The upper jaw was removed and the base of the skull scraped. The wound healed by primary union, and the patient left the hospital in a fortnight. About three years afterwards the patient came back with a recurrence, there being a large, open ulcer, with thick edges, which involved nearly the whole of his cheek. He was told that nothing further could be done for him, and he returned home. After a time the tumour underwent shrinkage, and in the course of five or six months it had entirely cicatrised. As to the question of its being a gumma, several competent microscopists were strongly of opinion that the appearances were those of a sarcoma. Other cases of this kind had been placed on record.—Dr. NEWTON PITT, in reply, remarked on the very small amount of growth that was present in this case compared with the amount of fluid.

Mr. H. W. PAGE related the sequel to a case of Syphilitic Cranial Necrosis recorded in the twenty-eighth volume of the Transactions of the society. The patient in July, 1894, had had compression of the brain and frequent convulsions, satisfactorily dealt with by trephining over the right Rolandic area and the removal of a large quantity of broken-down gummatous material from between the dura mater and the bone. A large piece of necrosed eroded bone was taken away at the same time. The lesions were obviously syphilitic. The patient returned to his work and was free from fits until early in November, 1895, when they suddenly returned and rapidly regained their former frequency, numbering from four to ten every hour. The fits seemed to begin in the left hand or the left angle of the mouth, but so quickly became general that it was impossible to be certain on this point. The site of the former operation was exposed, but no fresh disease was discoverable either there or in the immediate neighbourhood, and it was obligatory to desist from further exploration, as there was nothing in the symptoms to show where disease lay. It was strongly suspected that there was a cerebral gumma beyond surgical interference. The fits continued to increase in frequency and severity and in two days the man died exhausted. At the necropsy a large broken-down gumma, which it would have been impossible to remove, was found in the right frontal lobe.—Mr. CLEMENT LUCAS related the case of a woman who was supposed to have Cancer of the Breast. There was a ragged ulcer of one mamma exposing a costal cartilage. There was dulness over the lung on the same side, with the usual signs of pulmonary consolidation. Syphilis being suspected, she was given large doses of iodide of potassium without producing any appreciable result. Some weeks later she became subject to epileptic fits, in one of which she died. Post mortem the lung was found to be fibrous throughout, and a tumour was discovered growing from the dura mater and projecting into the frontal lobe. Other signs of syphilis were present.—Dr. CHAPMAN inquired if in Mr. Page's case the patient had been treated with iodide of potassium in the interval between the first and second attacks.—The PRESIDENT asked if an ophthalmoscopic examination was made on the patient's second admission. The lesion of the frontal lobe did not account for the motor disturbances, which were present up to the time of the fatal result. The tumour in the Rolandic area might really have been present when the patient was first seen, for such lesions had more than once been observed to exist without giving rise to any indication of their presence. Although fits might be relieved by an operation performed for epilepsy, yet they might return later perhaps because of the formation of cicatricial tissue at the site of the operation, and this cicatrix might act like a neoplasm and press upon the brain surface. Cases such as these were extremely difficult of explanation.—Mr. PAGE, in reply, said that the patient was put upon iodide of potassium when he left the hospital, but he had not followed systematic treatment. When first in the hospital large doses of iodide produced but little appreciable effect. It was possible that the fits might have been set up by the presence of the cicatricial tissue, but against this was the fact that the subjacent membranes were practically healthy. He referred to the case of a patient who suffered from fits due to some lesion in the Rolandic area, and in him the first indication of a gross lesion was the appearance of the growth through the scalp. It was syphilitic and was dealt with as in the case now related. The patient died from pyæmia and during the last illness the surface mischief gradually extended. He likewise mentioned another case at present in hospital of a boy who came in with a scalp wound which had been suppurating profusely for three weeks. On exploration a minute opening was found in the bone from which pus escaped. On trephining a large abscess was found in the frontal lobe, which was drained, and the child

Digitized by Google

was now nearly well. There had been no cerebral symptoms before the operation, but the boy's temperament had altered and he had become bright and cheerful. There had been no fever or paralysis.

OBSTETRICAL SOCIETY OF LONDON.

Supposed Miscarriage at the Sixth Week of Gestation.—Deciduoma Malignum.—Exhibition of Specimens.

AN ordinary meeting of this society was held on April 1st, Dr. CHAMPNEYS, President, being in the chair.

Mr. MALCOLM read notes of a case in which a Miscarriage at the Sixth Week of Gestation was supposed to have taken place on Sept. 28th, 1895. On Dec. 20th the patient became very ill. She was admitted to the Samaritan Free Hospital and a perforation of the uterus was discovered. Death occurred on the 24th. Post mortem new growths were found in the uterus, the right broad ligament, the mediastinal glands, and the lungs.—Dr. HEBB reported that the growths were sarcomatous, and showed sections.

Mr. ALBAN DORAN communicated (for Mr. RUTHERFORD MORISON) a case of Deciduoma Malignum occurring in England.

Dr. HERBERT SPENCER read notes of a case of Deciduoma Malignum. He gave a full clinical history and post-mortem record of a case of this kind occurring in 1889, the first case, he believed, observed in this country. The disease occurred in a young Danish woman twenty-seven years of age, a secundipara, whose previous labour took place at the age of twenty years. The first symptom of the disease—passage of masses of the growth—occurred twenty-eight days after a normal labour, which was followed by a normal puerperium. Subsequently there was a fœtid discharge of masses of growth and of blood, and the disease ran a septic course, terminating fatally within ten and a half weeks of delivery. At the necropsy an ulcerated and gangrenous growth was found at the placental site, the ulceration and gangrene having nearly perforated the fundus. Secondary growth was also found in the cervix and in the lungs, but nowhere else in the body. The growth in all three situations was similar and was characteristic of deciduoma malignum, being apparently a large celled sarcoma with the typical "syncytium." A full account of the microscopic appearances was given. The necessity of early diagnosis and treatment by vaginal hysterectomy was pointed out.

Dr. EDEN read a paper entitled "Deciduoma Malignum: a Criticism." He referred to the number of cases of malignant uterine growth occurring subsequently to gestation which have been recently recorded, mostly by German observers. The most important cases were those of Sanger, Gottschalk, Marchand, and Whitridge Williams. Sanger introduced the term "Deciduoma malignum." He thought that in his case the tumour arose in the decidua and was composed largely of so-called "decidual cells." Dr. Eden believed that cells precisely like those found by Sanger occurred in the uterus under various conditions, and did not prove the origin of the growth in the decidua. Gottschalk believed that in his case the growth arose from a "sarcomatous transformation" of the stroma of retained chorionic villi. Whitridge Williams's case possessed the general characters of a sarcoma; tumours were present in the uterus, vagina, and vulva, and it was not clear which was the primary growth. He relied for his diagnosis upon the presence in the tumours of plasmodial masses which he believed to be syncytial in origin. Marchand records two cases, in both of which he found similar syncytial masses; he also claimed to have found cells derived from the fœtal ectoderm. In one case represented as a tubal gestation in a girl aged seventeen years there was no anatomical evidence of pregnancy discovered. The tubal mass may therefore have been a primary malignant growth. Dr. Eden believed that plasmodia not unlike those figured by Williams and Marchand as syncytial masses were frequently found in sarcomatous growths in other parts of the body, and doubted whether there was sufficient evidence to justify the view that they arose from placental relics. The case recorded by Mayer was referred to in which there seemed to be proof of the origin of a malignant growth in retained myxomatous villi (hydatiform mole).

The following specimens were exhibited:—

Dr. WILLIAM DUNCAN: Hæmato-salpinx with Torsion of Tube.

Dr. SPENCER: (1) Modified Ferguson's Speculum; (2) a skiagram of a Sireniform Monster; and (3) lantern slides illustrating his paper on Deciduoma Malignum.

Dr. GALABIN: (1) Myxo-sarcoma from the Urethra in a Child; (2) Sarcoma of the Cervix Uteri; and (3) Microscopic Sections from Material removed from the Uterus after Miscarriage (? Malignant).

Dr. CULLINGWORTH: Ruptured Tube and a Three Weeks' Embryo from the Sac of an old Pelvic Hæmatocele.

EPIDEMIOLOGICAL SOCIETY.

Puerperal Mortality in England and Wales from 1847 to 1895.

A MEETING of this society was held on March 20th, Mr. SHIRLEY F. MURPHY, President, being in the chair.

Dr. W. WILLIAMS, medical officer of health of Glamorgan, read a paper on Puerperal Mortality in England and Wales from 1847 to 1895. The subject, he said, was one of national importance, for though the experience of lying-in hospitals had shown puerperal mortality to be eminently preventable the number of women dying in childbed had not diminished and was about 4000 annually. These deaths were referable: (1) to puerperal fever, and (2) to accidents of childbirth, such as exhaustion, hæmorrhage, and convulsions. Calculated on the number of registered births the mean annual death-rate was 4·9 per 1000, or 2·0 from puerperal fever and 2·9 from accidents. The puerperal fever death-rate attained the maxima of 3·6 in 1874 and 3·3 in 1893, the latter being a remarkably dry year in which the mortality from typhoid fever, diphtheria, and diarrhœa was very high. The highest death-rate from accidents during the period under review was 4·5 in 1847 and the lowest was 1·9 between 1886 and 1889. The apparent increase in puerperal fever about 1874–75, when the Public Health Acts came into force, might be the result of a more uniform nomenclature. In the successive periods ending in 1854, 1864, 1874, 1884, and 1894 the death-rates from puerperal fever were returned as 1·72, 1·56, 1·78, 2·28, and 2·53, and those from accidents as 3·01, 3·07, 3·03, 2·24, and 2·41, the latter showing a marked reduction during the last twenty years, but the former steadily rising. Deaths from puerperal fever were twice as frequent in early life, and those from accidents fewest between the ages of twenty-five and thirty-five, rising rapidly afterwards. Primiparæ were specially liable to puerperal fever. From the returns since 1884 it appeared that the mortality from puerperal fever, which was 2·0 per 1000 for the whole country, ranged from 2·4 in Lancashire and 2·2 in Wales, Cheshire, and Northumberland, to 1·0 in Surrey. The conditions of the population varied greatly within each county, but generally the mortality was higher in those west of a line drawn from the mouth of the Tees to that of the Severn. That from accidents of childbirth ranged from 4·1 in North and 3·7 in South Wales to 1·9 in Rutland, the mean being 2·9, the highest rates being in Wales and the border counties and the lowest in Essex, Hants, Leicester, and Rutland. Taking the Welsh counties severally, the death-rate from puerperal fever was above the average for England and Wales in seven counties and below it in four. The highest and the lowest total mortalities alike were met with in purely agricultural counties, though it seemed that the mountainous districts had the higher death-rates. The population of the county of Glamorgan had increased tenfold since the beginning of the century and had doubled within the last thirty years, comprising at present more than half that of the entire principality, or at the last census 693,072 persons, of whom not more than 25,000 or 30 000 lived under strictly rural conditions in the peninsula of Gower and the Vale of Glamorgan. From an analysis of the density of the population and the social conditions of each registration district the conclusion might be drawn that puerperal fever was generally, though by no means always, excessive in the most insanitary localities; that the mortality in the larger Welsh towns did not differ much from that of towns in other parts of the kingdom; and that the prevalence of puerperal fever in the thickly peopled mining valleys was to a very great extent due to the general employment of ignorant midwives. The death-rate from accidents of childbirth, which for the whole Principality was not much above that for the rest of the kingdom, was very unequally distributed, being excessively high in these mining valleys, where, however, there ought to be no serious difficulty in obtaining

Digitized by Google

medical assistance. In an epidemic of puerperal fever, of which a detailed account was given, the part played by the midwife was evident; the cases were chiefly among easy natural labours and primiparæ, and there was no connexion between this disease and scarlet fever which prevailed at the same time, the few parturient women who contracted scarlet fever being in no instance attacked by puerperal fever. Expectant mothers ought to be instructed in the duties and responsibilities of the puerperal state, and every woman should be taught the elements of nursing, with special reference to parturition and infectious diseases, for which, as a branch of technical education, classes should be formed by the county councils, who might also undertake the training of midwives whose practice should be, so far as possible, watched by the medical officer of health. Notification must be made universal, and on the occurrence of a case of puerperal fever the medical officer and his inspectors should forthwith see to the remedying of any sanitary defects and the disinfection of the premises, bedding, &c., suspending the midwife for a time.

Dr. WILLOUGHBY, pointing to the maps, maintained that no relation existed between the physical features of a district and the puerperal mortality. He did not believe that any specific fever, except erysipelas, could give rise to puerperal fever, and he attributed its frequent occurrence after easy natural labour to inefficient evacuation of the uterus. For many years he had always effected this completely by introducing his hand, and had avoided the exhaustion of tedious labour by using the forceps in the majority of his cases—precautions to which he ascribed the immunity of his patients from puerperal fever and hæmorrhage.

Dr. BOXALL held the same opinion as the last speaker with regard to erysipelas and other acute specific fevers. He could not explain why puerperal fever, although stationary in the provinces, seemed on the increase in London, where deaths from the accidents of childbirth were diminishing. The liability of primiparæ to laceration rendered them more susceptible of infection. He believed that it was useless to instruct ordinary midwives in antiseptic methods.

HUNTERIAN SOCIETY.

Perityphlitis.

A MEETING of this society was held on April 8th.

Mr. PERCY WARNER read a paper on a case of Perityphlitis. The patient, aged thirty-five years, was suddenly taken ill on July 24th, 1895, with pain in the renal region running in the direction of the ureter, marked tenderness in front and behind, vomiting, and rise of temperature. There was also a rigid condition of the muscles on the right side of the abdomen and frequent micturition. No well-defined tumour could be made out until convalescence was established. The patient had a relapse on Sept. 9th, with great pain and much swelling above the crest of the ilium. Mr. Charters Symonds operated and a quantity of foul pus was discharged. The patient made a good recovery. Mr. Warner remarked on the frequency of micturition, which at first suggested a renal origin of attack, but showed how the variability in length and position of appendix would account for the varying site of pain after suppuration has taken place. The position of the pain depends on the position of the abscess, which in the case related was situated at a point on the crest of the ilium at the junction of the posterior and middle thirds, where the abscess had burrowed out of the iliac fossa into cellular tissue of the gluteal region. The tenderness behind was remarkable. He pointed out that the treatment of this disease might be divided under the three forms of the malady: (1) Simple perityphlitis; (2) perityphlitic abscess, probably due to perforation; and (3) perityphlitis followed by general peritonitis due to acute perforation. The great difficulty consisted in deciding when to operate, and he remarked that no two symptoms can determine this, and that he relied not only on local signs, but also greatly on the general condition of the patient. He also referred to the important question of surgical treatment in the early stage and quoted the opinion of American surgeons, who advocated the removal of the appendix in all cases of perityphlitis. Lastly, he pointed out that in cases of relapsing typhlitis there was a fair consensus of opinion that the operation should be done in the quiescent period.

Mr. CHARTERS SYMONDS, after making supplementary remarks as to the operation, gave an account of his experience in such cases and referred to the fact that symptoms of perityphlitis were simulated sometimes by malignant disease, suppurating kidney, and active mycosis, and are occasionally apt to resemble typhoid fever. He considered it doubtful whether in acute cases an operation can be performed too early, and showed a perforated appendix removed from such a case with successful result.

The PRESIDENT, Dr. F. J. SMITH, Dr. H. SEQUEIRA, Mr. HOPE GRANT, and Dr. ARTHUR DAVIES took part in the discussion, and Mr. WARNER replied.

BRITISH GYNÆCOLOGICAL SOCIETY.

Adjourned Discussion on Ventro-fixation and Suspension of the Uterus and Allied Operations.—Exhibition of Specimen.

A MEETING of this society was held on April 9th, Dr. CLEMENT GODSON, President, being in the chair.

Dr. BANTOCK said he had never performed any of these operations. He had been able to afford complete support in all uncomplicated cases by means of a properly constructed diaphragm pessary with or without a plastic operation. When he opened the abdomen it was never on account of displacement, but on account of the condition of the appendages.

Mr. MAYO ROBSON read a short paper (communicated by Mr. Reginald Harrison) by Dr. O'Conor of Buenos Ayres, giving his experience of Ventro-fixation of the Uterus, which he had performed eight times with satisfactory results.

Dr. ELDER (Nottingham) had performed Alexander's operation in several cases some years ago, but gave it up for three reasons: (1) the uncertainty of finding the round ligaments; (2) the results were not permanent; and (3) it was not devoid of risk. In uncomplicated cases he had found curetting and plastic operation sufficient, and, like Dr. Bantock when he opened the abdomen in cases of adhesions, it was not because of the displacements, but because of the condition causing it. He had seen many fashions in gynæcology, and he thought that ventro-fixation was one of them which would not last.

Dr. ALEXANDER (Liverpool) thought his operation had not been quite fairly represented by some of the speakers at the last meeting and he wished to correct two impressions: (1) that it was a double abdominal section; and (2) that the results were not permanent. 1. He recapitulated the steps of the operation, showing that the abdominal cavity was not opened, and maintained that there was absolutely no risk in it, but some of the modifications of it which had been introduced were both unnecessary and dangerous. 2. Results: The cases of failure were due to want of attention to certain details. In cases of prolapse a plastic operation was often necessary, but he could not agree with Dr. Bantock's pathology of the condition. The first step in prolapse was the falling back of the uterus, and his operation cured this, not by drawing up the uterus, but by anteverting it. When there was retroversion he always inserted a Hodge pessary to keep traction off the round ligaments till they were firmly united in the wound. It was easy to tell when union had occurred, because pressure on the external abdominal ring caused traction on the cicatrix. When the uterus was also retroflexed he introduced a stem pessary for three weeks, keeping the patient in bed. In some of his earlier cases, where these precautions were not adopted, the condition recurred owing to tension on the yet ununited ligaments. He then gave in detail the after-histories of a number of his cases and said he felt justified in maintaining that the operation was efficient. He had in all performed several hundred operations. He admitted that there was a slight tendency to hernia in some cases, but had always found that this tendency, when it existed, could be readily controlled by a truss.

Dr. WINSON RAMSAY (Bournemouth) showed a Uterus from a patient aged fifty-five. In February, 1894, he performed ventro-fixation for prolapse. A year later she returned with the cervix protruding through the vulva. Thinking that the stitches had given way he performed hysterectomy, but then found that the cervix was elongated and that the fundus was still firmly attached to the abdominal wall. She made a good recovery.

Dr. WILLIAM DUNCAN, speaking at the President's invitation, said that Dr. Ramsay's specimen was interesting as

Digitized by Google

illustrating supra-vaginal elongation of the cervix; but he presumed the condition existed at the time of the first operation. His experience of Alexander's operation was very different from that of Dr. Alexander; he performed it eleven times some years ago. Unlike Dr. Elder, he found the operation itself quite simple, but all the cases relapsed within four months. He did not use a stem pessary because he regarded it as a dangerous instrument.

Dr. LEITH NAPIER remarked that the first patient he operated on was now pregnant for the third time. He asked Dr. Alexander whether he found his operation practicable when there were adhesions; it seemed to him that in such a case the round ligaments might be ruptured, as happened twice to Edebohls of New York. He did not think more than three sutures were necessary in ventro-fixation; if the adhesions were too firm trouble arose during pregnancy.

Dr. HEYWOOD SMITH used only one suture in his first case, which was quite successful. The discussion illustrated the progress of public opinion, for he performed the first case of deliberate ventro-fixation twenty-two years ago, and THE LANCET in commenting upon it hoped that as it was the first it would be the last.

Dr. ALEXANDER, in reply to Dr. NAPIER, said that he operated at once when there were no adhesions; but when these were present he treated them by rest in bed with douches and tampons, by which they were readily overcome. He did not consider there was any danger in the stem pessary; as he used it he kept it in only while the patient was in bed.

The PRESIDENT, in thanking Mr. Mayo Robson for coming up to London a second time at considerable personal inconvenience, said that the debate had shown that the operation of ventro-fixation was not one to be put aside, but to be used with proper limitations.

Mr. MAYO ROBSON, in reply, thanked the Fellows for their attention and for their interest in the debate. If these operations were not safe they should not be done; but the discussion had demonstrated their safety. When they could cure a patient without operation they should do so, but many cases would only yield to operation.

Dr. WINSON RAMSAY (Bournemouth) showed a Pedunculated Myoma of the Uterus which occupied the pelvis and led to intestinal obstruction.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Infantile Scurvy.—Chemical Composition of the Carbohydrate and Albumoid Substances.—Exhibition of Cases and Specimens.

A MEETING of this society was held on April 10th, Dr. A. SYMONS ECCLES, President, being in the chair.

Dr. H. MENZIES read notes on a case of Infantile Scurvy. The patient was a male infant aged eleven months, the younger child of healthy, well to-do parents. He was well grown and until the present attack had always been healthy. After a few days' malaise on Feb. 18th of the present year his left eye suddenly swelled and became discoloured and all the classical signs of the disease rapidly developed—viz., loss of strength, pallor, limb swelling, exoptosis of the left eye, spongy gums, bruise-like ecchymoses, and minute purpuric spots. A rapid disappearance of all the symptoms followed the administration of an anti-scorbutic dietary of fresh milk, raw meat juice, potato pulp, and orange juice. The case was interesting in two ways: (1) the absence of all positive signs of rickets; and (2) the danger of a long-continued use of sterilised milk, upon which the child had been brought up. After referring to the writings of Dr. Cheadle and Dr. Barlow on the subject, Dr. Menzies pointed out the curious fact that while authorities in England and America agree in recognising the scorbutic nature of the affection, many German and some Danish writers still regard as unproved his etiological factor, and maintain that rickets *plus* a hæmorrhagic tendency is the real malady—a view which seems to be opposed to all the evidence of its morbid anatomy and certainly contradicted by the result of dietetic treatment, for the rapid improvement which follows the administration of anti-scorbutics is one of the most remarkable facts in medicine.—Mr. ALBAN DORAN doubted whether sterilised milk was wholesome and nutritious, and suggested that some of our efforts at the exclusion of germ life might be misdirected.—Mr. KEETLEY considered that the advantages of giving sterilised food to infants quite outweighed its dangers, which could be averted by the addition of a due proportion of anti-scorbutics. He affirmed the distinction between infantile scurvy and rickets, which latter might be produced by more than one micro-organism, including that of syphilis.—Dr. H. SUTHERLAND believed that from a scorbutic standpoint the boiling of milk as usually practised was probably harmless, but the use of milk exposed to a very high temperature for a long time was not to be regarded as safe.—Dr. COUTTS believed that the milder forms of infantile scurvy were common and frequently unrecognised. He advocated the addition of anti-scorbutics to sterilised milk.—After remarks by Dr. THUDICHUM, Dr. BURRELL, Dr. KEEN, Mr. MORTIMER, and the PRESIDENT, Dr. MENZIES replied.

Dr. THUDICHUM read a paper on the Chemical Composition of the Carbohydrate and Albumoid Substances with special reference to Diabetes and its treatment.

Dr. DICKMAN showed a case of Localised Scleroderma.

Mr. ALBAN DORAN showed three specimens of True and False Capsules of Ovarian Cysts. 1. The patient was single, aged twenty-five. A small cyst filled the lower part of the abdomen and intestine lay in front; the fundus of the uterus could be felt in the right groin. No part of the cyst came down into the pelvis. On tapping a pint and six ounces of fluid escaped. On inspecting the tapping hole two distinct layers could be seen as though there were a true capsule. On pushing the hand down behind the supposed capsule the entire cyst was displaced with a normal pedicle. There were no adhesions and the opposite ovary was healthy. The "capsule" was simply the ovary itself distended by the cyst within its substance. The true cyst wall was connected with the ovarian capsule by very loose connective tissue. Had the union been close and firm that would have been the usual condition in ovarian cystoma and no two separate layers would have been seen on inspecting the trocar wound. On the other hand, had the capsule of ovarian tissue been adherent to pelvic structures the cyst might have been deliberately enucleated from the ovary itself; the appearance after enucleation would then have been puzzling. 2. Hypertrophied Tube on the Surface of an Inflamed Ovarian Cyst. The meso-salpinx adhered firmly to the cyst, so that at first the cyst seemed as though it had furrowed into its layers. This was a "false capsule cyst." 3. A Dissection showing the relations of a Cyst developed between the Folds of the Meso-Salpinx. The greatly elongated Fallopian tube runs on the surface of the wall of a similar but very much larger cyst, the greater part of which has been cut away. These are typical encapsuled cysts. Mr. Doran remarked on the non-identity of pathological and surgical cysts and on the grave results which might ensue on their confusion, for if the surgeon mistook these adhesions for a capsule and attempted enucleation, intestine, vessels, or the uterus might be damaged.

MIDLAND MEDICAL SOCIETY.

Exhibition of Cases and Specimens.—Pneumothorax.

A MEETING of this society was held on March 18th, Dr. UNDERHILL, the President, being in the chair.

Dr. J. HAZELWOOD CLAYTON showed a youth aged nineteen years who presented Enlargement, without evidence of secretion, of the Right Mammary Gland. The question discussed was whether the case ought to be regarded as one of inflammatory enlargement or as one of true hypertrophy induced by intermittent pressure from a carpenter's brace.

Mr. F. MARSH showed a little girl aged five years who last autumn had Scarlet Fever, followed by Post-scarlatinal Diphtheria (membranous laryngitis), necessitating tracheotomy. During convalescence she contracted measles. Attempts were made on several occasions to dispense with the tracheotomy tube, but without success, as asphyxia immediately became imminent. She was first seen by Mr. Marsh on Nov. 30th, and a laryngoscopic examination was made under chloroform. Considerable cicatricial stenosis somewhat cone-shaped was found in the upper part of the larynx, and a small probe only could be passed through into the trachea. On Dec. 11th the cicatrix was divided with Heryng's intra-laryngeal knife and a next to the largest size O'Dwyer's intubation tube introduced, the smaller sizes being expelled, probably owing to the shape of the opening. The tracheotomy tube was now removed and

Digitized by Google

the wound rapidly healed. On the 30th the intubation tube was removed, but as asphyxia threatened the largest size O'Dwyer's tube was inserted. It was decided to leave this in for a fortnight and then, if it could not be dispensed with, that a thyrotomy should be performed and the cicatricial bands excised. Unfortunately, on Jan. 8th symptoms of typhoid fever were noticed and a typical attack ensued. As the child was fairly comfortable and respiration was not embarrassed the tube was allowed to remain in the larynx until March 13th. Its removal on this occasion was successful, both respiration and phonation being more easily performed. Up to the date of publication (March 30th) steady improvement has taken place; there is only slight dyspnœa when the child runs fast, and the breathing is occasionally noisy during sleep. The voice, too, is improving; it is usually a hoarse whisper, but at times becomes louder and clearer.—Mr. F. MARSH also showed a youth aged twenty years who from childhood had had a purulent discharge from the right ear (a sequel of measles) and at intervals an abscess in the mastoid region. When admitted into the Ear and Throat Hospital pus was freely discharging from a sinus opening about half an inch above the external auditory meatus. He had never had any headache or illness, the only symptoms experienced being the purulent discharge and some slight pain with each abscess formation. The mastoid was explored on Feb. 22nd and beneath the orifice of the sinus was an opening in the bone about half an inch in diameter leading into a large cavity filled with fœtid putty-like débris. When this was removed the cavity was found to be quite two inches in diameter and would have held a Tangerine orange. The walls were of bone except posteriorly, where the cerebellum could be felt pulsating over an area about the size of a four-shilling piece. The upper limit was quite an inch above the superior wall of the meatus. The cavity was lightly packed with gauze and was now slowly granulating. The features of interest were the unusually large dimensions of the cavity and the total absence of sinus, meningeal or cerebral complications, although the meninges were in contact with the fœtid contents.

Mr. GEORGE HEATON showed a Sixpence which had suddenly been Expelled from a man's Right Bronchus five and a half years after it had been inhaled. The patient had suffered from repeated attacks of suffocative cough ever since swallowing the coin. A low tracheotomy was performed in 1891 and attempts made to remove the coin. He suddenly coughed it up in January last and has since lost all his symptoms. The coin was in three pieces and thickly coated with black scales of sulphide of silver.

Mr. HEATON also showed a large Uterine Fibro-myoma removed by Hysterectomy. The tumour, which weighed between ten and eleven pounds, reached as high as midway between the umbilicus and ensiform cartilage. It had lately grown rapidly and reduced the patient to a state of profound anæmia. The pedicle was treated extra-peritoneally with the clamp. The patient experienced little or no shock from the operation and was at present convalescent.

Mr. GAMGEE showed a specimen of Perforated Vermiform Appendix removed from a girl aged fifteen years. The symptoms began on March 1st, 1896, with a sudden attack of abdominal pain, but no vomiting. The pain continued for a week, when she presented well-marked signs of localised inflammation in the right iliac fossa. At the operation on March 8th four or five ounces of foul pus were evacuated and the appendix was removed. Vomiting, collapse, and death occurred nine hours afterwards. The post-mortem examination revealed general suppurative peritonitis. Attention was called to the absence of symptoms of general peritonitis, for the patient's condition appeared good. There was no vomiting till an hour or two before death, the abdomen moving freely. There was no general abdominal pain or tenderness.

Dr. SHORT showed a youth aged seventeen years (but who looked fourteen years) with a large Pulsating Tumour between the clavicle and the right edge of the sternum. There was loss of resonance on percussion, with a distinct thrill; presystolic and systolic mitral and aortic diastolic murmurs were present. Dr. Short thought that a saccular dilatation of the aorta existed between the valves and the arch, probably due to some congenital defect because the boy was of stunted growth; dyspnœa and slight cyanosis on exertion had existed since birth; and the general absence of symptoms was inconsistent with any recent origin.

Dr. SHORT also showed the Heart and Lungs from a baby four weeks old. There were beady vegetations on the curtains of the tricuspid valve which were thickened, two of them being joined together. The pulmonary valve was not affected. The left side of the heart was normal. From the appearance of the valve it was inferred that the endocarditis had commenced during fœtal life and had affected an imperfectly developed valve. The condition was a rare one. Death occurred somewhat suddenly at the end of the fourth week and was preceded by five attacks of acute dyspnœa unaccompanied by cyanosis. Portions of the lungs were imperfectly expanded.

Dr. FOXWELL read a paper on four cases of Pneumothorax occurring in healthy males who had suffered no previous illness or external violence. He believed the cause in each was the same—viz., the rupture of an emphysematous air sac. Recovery occupied from twenty to four weeks. The longer period was partly brought about by a relapse owing to unwise exertion and partly to the age (sixty years) of the patient. The patient who got well in four weeks was only nineteen years of age. In his case, too, two pints of gas were drawn off. Dr. Foxwell pointed out that, in his opinion, the chief cause of the re-expansion of the lung was the cohesive force of the two pleuræ, a force which was demonstrated by Dr. S. West in his Bradshaw Lecture to be nearly double the elasticity of the expanded lung. Regarding treatment, the importance of respiratory quietude and the advantage of removing the gas under the same circumstances as one would a liquid effusion were insisted upon.

MANCHESTER MEDICAL SOCIETY.

Treatment of Recurring Appendicitis. — Intra-laryngeal Photography. — Sensory Distribution of Spinal Nerve Roots.

A MEETING of this society was held on April 1st, the President, Dr. HENRY ASHBY, being in the chair.

Mr. SOUTHAM mentioned ten cases of Recurring Appendicitis treated by operation. In five cases the appendix was removed during the quiescent stage with satisfactory results. In one case, where the appendix was so surrounded by dense adhesions that it was unrecognisable, relief followed the breaking down of adhesions. Attention was directed to the fact that it was not uncommon for suppuration to occur sooner or later in recurrent appendicitis, and it was therefore advised that in order to prevent this complication the appendix should be removed after two well-marked attacks, especially if any induration or local swelling persisted after the subsidence of the attacks. In support of this opinion details were given of four cases of recurring appendicitis where suppuration had taken place; in three of these an encysted intra-peritoneal abscess was opened and drained with good results; in the fourth case, where there was a history of mild attacks recurring for several years, perforation of the appendix suddenly took place, followed by diffuse suppurative peritonitis, which proved fatal.

Dr. YONGE discussed the difficulties of Intra-laryngeal Photography. There was first the difficulty of obtaining a good actinic light of sufficient power to illuminate satisfactorily a cavity within a cavity such as the larynx happened to be. Direct sunlight was unavailable, magnesium light uncontrollable and otherwise inconvenient, and therefore an electric arc lamp was chosen for his experiments. Other difficulties were that of directing all the available light into the mouth, of illuminating the laryngeal mirror when it was so placed in the pharynx as to receive the complete laryngeal image, and the difficulty of holding the mirror in the patient's mouth so that it should appear illuminated to the lens of the camera, although to the operator's eye it might be in shadow owing to the fact that the angle at which his eye caught the illuminated image was different from the angle at which the lens received it. Other difficulties were gauging the exact length of exposure required and, lastly, keeping the mirror absolutely steady. The method adopted by Dr. Yonge—based on Mr. Lennox Browne's—was as follows. Dr. Yonge, who performed the experiments on his own larynx, seated himself before a camera into the cap of which a small looking-glass had been inserted. A large laryngeal mirror was introduced with the left hand and the tongue drawn forward with the right. The light of a 1000-candle power electric arc lamp—supplied by the Edison Swan Company—was then concentrated by passing the.

Digitized by Google

rays through a 6-inch condenser and directed on the mouth. The carbons of the arc lamp were mounted on a projector and the whole apparatus formed a species of "search-light." As soon as the mirror was seen to be sufficiently illuminated by the reflection in the small looking-glass placed on the cap a signal was given, the cap removed, and an exposure of one second allowed. Photographic laryngoscopy was of value (1) as showing the exact method of voice production; (2) as giving a truthful account of endo-laryngeal conditions; and (3) as a means of estimating the progress of a laryngeal case. Dr. Yonge gave a short lantern demonstration of photographs obtained by the foregoing method.

Mr. THORBURN then read a paper on the Sensory Distribution of Spinal Nerve Roots.

LIVERPOOL MEDICAL INSTITUTION.

Cell Granulations.—Exhibition of Specimens.—Leprosy in Iceland.

THE last meeting of the session was held on April 9th, Dr. BARR being in the chair.

Dr. BUCHANAN read a note upon Cell Granulations. He especially drew attention to the fact that in some of the white blood corpuscles two kinds of granules, basophil and oxyphil, were present. This, he said, had not been observed before. The paper was illustrated by some beautiful lantern slides.

Mr. LARKIN exhibited a Brain with a Temporo-sphenoidal Abscess following Middle-ear Disease; also a Pedunculated Tumour which he had removed from the neighbourhood of the nipple in a female subject. Mr. Hutchinson had reported three similar cases which proved to be adenomata. Mr. Larkin had not yet examined this tumour microscopically.

Dr. MOYLES showed for Dr. ALEXANDER: (1) Hernia through a Hole in the Mesentery, and (2) Syphilitic Disease of the Skull, &c.

Dr. ABRAM exhibited a Fibroid Heart and Thrombosed Femoral Artery. The latter had led to dry gangrene of the leg. Microscopical sections of the coronary arteries and the femoral revealed extensive disease of the interior and middle coats of both vessels.

Dr. GROSSMANN then read a paper upon Leprosy in Iceland. He narrated the history of the disease as given in the Icelandic chronicles, and pointed out that in the sixteenth century leprosy was frequently met with. He stated that leprosy was much more common in Iceland than was generally supposed, probably owing to the non-recognition of the anæsthetic variety. He did not believe in the hereditary transmission of the disease, at least to any extent, but considered it to be transmitted by contagion, a mode of propagation favoured by the almost indescribably bad hygienic conditions under which the majority of the Icelanders live. Dr. Grossmann illustrated his remarks by a series of excellent photographs of the anæsthetic and tuberculated varieties of leprosy.—Dr. HARRIS said that Dr. Haussen believed firmly in the contagious nature of the disease, and did not consider that bad hygiene and feeding had much influence.—Dr. ABRAM thought that hygienic conditions such as Dr. Grossmann had described, must afford a very good incubating machine for the bacillus lepræ. An analogous state of affairs is seen in beri-beri, where sailors keep the forecastle at such a temperature that some ships are never without cases on board, yet it never spreads among the saloon passengers.—Dr. LESLIE ROBERTS and Dr. BARR also took part in the discussion.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Suppurative Cholangioitis.—Pathological Changes in the Cerebral Cortex of the Insane.

A MEETING of this society was held on March 26th, the President, Dr. PORTER, being in the chair.

Mr. SNELL introduced a patient aged thirty-three years, the subject of Acquired Nystagmus, due to the manner of work followed at his occupation. The man had been compelled to relinquish his employment on two or three previous occasions for lengthened periods owing to the distress occasioned by the subjective symptoms of the nystagmus. Mr. Snell referred to nystagmus in other occupations, remarking that if looked for the affection would be found to be associated with other employment and not entirely that of coal-mining. Since he had recorded some years ago the case of a compositor with acquired nystagmus he had met with other cases in the same class of work and had observed a fairly large number of instances in other occupations.—Mr. Snell also showed a girl aged eighteen years with Double Papillitis (passing into Atrophy), the result of plumbism due to her work as a file-cutter.

Dr. SINCLAIR WHITE showed a very large Gall-stone which he had removed by operation.

Dr. ARTHUR HALL showed specimens of (1) a Cerebellar Tumour the size of a hen's egg, sarcomatous, with secondary distension of the lateral and third ventricles to a very large extent. The affection had lasted eighteen months, and the gradual enlargement of the head was watched. Lumbar puncture was performed by Mr. Pye-Smith, but without benefit; in fact, it aggravated the pain and the boy died the following day. Two drachms of fluid were removed. 2. Hæmorrhage into the Pons extending over the base of the brain and into the left lateral ventricle. 3. Softening of the Right Optic Thalamus.

Mr. MARRIOTT showed: (1) An Intra-pericardial Rupture of the Aorta which showed marked atheromatous changes, and which was the seat of a small aneurysm at the point of rupture; and (2) a large Gall-stone from a patient under Mr. Lockwood's care which had been passed by the bowel without any symptoms.

Dr. ERNEST KNIGHT (Rotherham) read notes of a case of Suppurative Cholangioitis. The patient, a man aged forty-seven, fell ill at the end of October with symptoms of hepatic colic. The illness began with rigors and profuse sweating; slight jaundice was noticed two days after the onset of symptoms. It passed off in a week. The rigors persisted, however, and glycosuria developed. There were considerable tenderness and fulness in the epigastric region. The glycosuria intermitted for a time, but reappeared one month before death, the rigors and sweats continuing daily and nightly up to the time he died comatose, which was in January, 1896. There was no return of jaundice; there were varying tenderness and fulness in the epigastric region. No operative measures were deemed advisable. Post mortem the liver was found to be much enlarged, the cystic duct entirely and the common duct partly blocked by several soft gall-stones, consisting largely of colouring matter, each about the size of a horse bean. The gall-bladder was empty except for a little thick bile. Suppuration extended up the ducts through both right and left lobes and formed numerous small abscesses; the lobulus quadratus was converted entirely into an abscess cavity. The kidneys were small with atrophy of the cortex.

Dr. RAY (Wadsley) read a paper on Some Pathological Changes in the Cerebral Cortex of the Insane. Some introductory remarks were made on the fresh method of preparing brain sections, on the minute anatomy of the cerebral cortex, and on the neuroglia, its lymphatics and vascular system. The relation of the blood-supply to pathological changes was then dwelt on. The early changes in the cortex in insanity were described. The three stages of fuscous degeneration were illustrated by microscopical drawings and slides. Spider cells in the superficial layer of the cortex were demonstrated, and the nature and probable function of Deiters' cells were discussed. The paper concluded with some remarks on the nerve cell in idiocy.—The PRESIDENT, Dr. ARTHUR HALL, Mr. CUFF, Dr. BURGESS, Dr. ADDISON, Dr. SINCLAIR WHITE, Dr. RUTHERFORD, and Dr. MARTIN made remarks.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Defective Metabolism in its Relation to Gout.—Acute Dysentery.

A MEETING of this section was held on March 27th, Dr. T. W. GRIMSHAW, President, being in the chair.

Dr. M. A. BOYD read a paper on Defective Metabolism in its Relation to Gout, in which he pointed out the interdependence of the great physiological systems on each other, and the probability of defective metabolism in any one of these systems being followed by derangements of the others. The defective metabolism that led to the formation of uric acid in excess was not confined to the digestive system alone,

Digitized by Google

but might originate also in either the circulatory, the nervous, or the lymphatic systems. Harbaczwski considers that the circulatory system contributes the chief share of this excess and has come to the conclusion that uric acid was the metabolic product of nuclein derived from leucocytes, grounding his conclusion on the increase of this acid in the blood and urine in leukæmia and pernicious anæmia. If this observer's conclusions be correct Dr. Boyd considered that the formation of uric acid must be intimately associated with both blood destruction and formation, and if uric acid is due to a leucolysis it must materially interfere with the contributory aid of the leucocytes in blood formation, and so account for the anæmia present in many of the forms of atonic gout.—Dr. WALTER SMITH agreed with Dr. Boyd in considering gout as a deeply-seated perversion of the nutrition of the body. Gout is coincident in many cases, but not in all, with the deposition of sodium biurate in certain tissues, especially connective tissue. The cause of the apparent or real accumulation of uric acid in gout is not known. The amount of uric acid varies within wide limits both in health and disease, and the causes of its variations are not known. The assumption that there is an increase of uric acid in a gouty person rests upon six experiments, five of which were made many years ago by a faulty process. There is no evidence to prove that uric acid is a poison analogous to an alkaloid. Dr. Smith agreed with Sir William Roberts in believing that the alleged acid dyscrasia in gout is no more than an assumption.

Dr. FINNY described an outbreak of Acute Dysentery which occurred in September, 1889, among the members of a family consisting of seven persons. Five were attacked, and two died—a female aged seventy years and an infant aged eleven months. The ages of the others were thirty-seven, forty-nine, and twelve years respectively. The first case began on September 12th, lasted fifteen days, and ended fatally. The second case occurred two days after the first, lasted fourteen days and terminated in recovery. The third patient fell ill on Sept. 19th and died in four days. The fourth patient fell ill also on Sept. 19th, and after nine days recovered; the fifth fell ill on Sept. 21st and recovered after seven days. No other inmate of the house (and there were several) was ill before, during, or after the outbreak, and no cause could be suspected except that for two days before the outbreak milk was used which had been supplied by a friend whose child was reported to have died on September 14th of intestinal disease. The family had just returned in perfect health from spending the summer at the seaside. It is probable that the latter cases contracted the disease by contagion. The treatment consisted of bread or arrowroot in boiled milk, chalk and opium, and for the pains laudanum enemata. Ipecacuanha in twenty-grain doses was given to two cases, but seemed to have no controlling effect, and the same may be said of every kind of astringent used. Recovery coincided with the passage of a formed fæcal motion. While discussing the treatment of dysentery Dr. Finny said that Mr. William Arthur Dickson, F.R.C.S.I., treated 183 consecutive cases without ipecacuanha and without a death in the Government Hospital of British Guiana during the year 1893.—Dr. LITTLE said that his experience in India was to the effect that the astringent treatment was not useful in India, but quite the reverse, and that the ipecacuanha treatment of virulent acute dysentery produced results unattainable by any other means. Vomiting after twenty-grain doses was very rare, unless in the first dose or unless opium was present as in pulv. ipecac. co. When pure and given in a little arrowroot ipecacuanha very seldom caused sickness. After the patient had an evacuation twenty minims of liquor opii sedativus in about two drachms of warm milk was injected with a small glass syringe into the rectum. If the patient had not a motion he was first given a warm water enema and subsequently the opium. In chronic dysentery he gave one-grain dose each of ipecacuanha and extract of hyoscyamus in pill—from three to twelve being given in the day—and the patient put on a milk diet. At about the same time as Dr. Finny's cases occurred there were several cases in the Adelaide Hospital which presented all the symptoms of tropical dysentery, and the diagnosis was confirmed by post-mortem examination.

SECTION OF OBSTETRICS.

Tubal Pregnancy.—Suppuration of Ovary.—Exhibition of Specimens.

A MEETING of this section was held on March 6th, Dr. LOMBE ATTHILL, president, being in the chair.

Dr. ALFRED SMITH read notes of a case of Ruptured Tubal Pregnancy, with Hæmatocele of the opposite side, successfully operated on by him in St. Vincent's Hospital. The chief points of interest were the question of diagnosis and the pathological condition found during operation. There was no history of pregnancy; the menstruation was quite regular up to the very day when the patient was first seized with the abdominal pain and heavy menstrual flow. The pain was referred to the lower part of the abdomen, but was not so severe as to cause the patient to collapse; she was, in fact, able to walk to the hospital without assistance, although, on vaginal examination, nearly all the typical signs of ruptured tubal pregnancy were present. The condition on the right side was an example of "tubal abortion." The cyst on the left side was full of blood and had all the appearances of a tubal pregnancy, but the microscopic examination by Professor M'Weeney proved it to be an hæmatosalpinx.—Professor M'WEENEY said the dilatation on the left side resembled a case of tubal pregnancy. There were, however, a few points of difference: the walls in this case were thinner than they would be in a case of pregnancy, neither were they coated to the same extent with blood clot. If the contents consisted of clear serous fluid he (Professor M'Weeney) would have but little hesitation in describing the case as one of hydrocele. He found pus cells in the walls, from which he inferred that the tumour was inflammatory in its origin.—The PRESIDENT said that under any circumstances he would operate in a case of tubal pregnancy, and he mentioned the case of a woman who, after the lapse of twenty years, was expelling fœtal bones from her vagina.

The HONORARY SECRETARY read (for Dr. PUREFOY) a paper on a case of Suppuration in an Ovary the result of direct violence. The patient was twenty-one years of age, in good condition and of healthy aspect, and sought advice in February, 1895. The history of her illness was that in October, 1891, a child jumped on her as she lay in bed, causing her much pain in the left ovarian region and in the left leg. Immediately afterwards she became unwell for some days, and during the succeeding four years, till she came under Dr. Purefoy's care, menstruation continued profuse, irregular, and attended with so much pain in the lower abdomen and left leg that much impairment of her general health ensued. The uterus was enlarged and much retroverted, and the left ovary was enlarged, very sensitive to pressure, and somewhat prolapsed. The right ovary appeared to be normal and healthy. Removal of the left ovary was followed by an easy convalescence, and menstruation now recurs regularly without pain and is normal in amount, though for some months there was occasional severe pain in the left side and left leg.—The PRESIDENT regretted that they had not before them the report of a pathologist on Dr. Purefoy's case, as suppuration of the ovary was a very rare occurrence indeed.

Dr. JELLETT showed the following specimens for Dr. W. J. SMYLY:—(1) Four Myomatous Uteri removed by panhysterectomy; (2) a large Papillomatous Cyst removed from the right mesocolon; (3) Tubes Removed for Double Pyosalpinx and for Tuberculous Disease; (4) Hæmatosalpinx probably Originating in a Tubal Pregnancy, although no trace of an ovum had been discovered; and (5) Tubal Pregnancy Complicated with Gangrene of the Intestine six inches of which were removed, the canal being restored by Senn's bone plates. All these patients have either recovered or are progressing favourably

---

THE EPSOM WATER-SUPPLY.—The Epsom urban council is asking for powers to borrow £11,500 for works of water-supply—viz., the extension of the scheme which was set on foot two years ago, when a loan of £2500 was sanctioned to provide a new engine and boilers at the works. The present reservoir holds some 120,000 gallons, and it is proposed to erect a second on the Downs near the Derby Arms Inn. The site will cost £500, while an alternative site at Tattenham Corner would cost about twice that sum. The consulting engineer, Mr. George Hodson, said that a site in Langley Bottom, about a mile west of the Grand Stand, would be the best for the purpose if another reservoir were needed, but he was of opinion that the present water-works in East-street were free from pollution, and might properly be extended to the advantage of the ratepayers and on a more economical principle.

Reviews and Notices of Books.

Practical Studies in Fermentation. By EMIL CHR. HANSEN, Ph.D. Translated by ALEX. K. MILLER, Ph.D. London: E. and F. N. Spon. 1896.

TWELVE years ago Dr. Hansen of the Carlsberg Laboratory, Copenhagen, made an announcement of the greatest importance to the brewing industries. It has since led to important advances in other branches of industry, and it is hardly possible to estimate what will be the limits of further applications. We refer, of course, to Dr. Hansen's great discovery of a new analytical method and the certain demonstration that some of the commonest and most serious diseases of beer, such as yeast turbidity and objectionable changes in flavour, were caused, not by bacteria, but by certain species of yeast. This led to the elaboration of a method by which Dr. Hansen obtained pure cultures of systematically selected yeasts by a dilution method, with the result that the following important practical advantages in the brewing of beer were gained: 1. A definite result and rational working are secured where formerly everything depended more or less upon chance. 2. Maladies in the beer causing great losses are guarded against. 3. A yeast is obtained of higher commercial value than the ordinary impure yeast. 4 It places the industry upon a higher basis. The method did not, however, cease in its application to brewing. It has since been applied to other commercial processes. Pure cultures have been employed for the definite and wholesome souring of cream, for the manufacture of wine, cider, &c., and for the improvement of tobacco, which by inoculation prior to fermentation with bacteria occurring in Havanna and other superior kinds of tobacco may be made to acquire a superior aroma and a milder flavour. Dr. Hansen's book, admirably translated by Dr. Alex. Miller, is not, however, confined to the mere technique of industrial fermentative processes. It is, in addition, an important and interesting contribution to the life-history of micro-organisms. English readers have long heard of the remarkable researches and discoveries of Dr. Hansen, but have hitherto been debarred from reading in their own language the fascinating and historical sketch contained in the volume before us. A word of praise is therefore due to the translator for placing Dr. Hansen's "Untersuchungen aus der Praxis der Gärungsindustrie" before the English industrial and scientific public. Home manufacturers are notoriously conservative in connexion with the introduction of improved processes, but this is in a great measure due to ignorance and the absence of a clear conception of the advantages promised. We fear this ignorance is often wilful. Dr. Hansen's pure culture method, securing at all times a uniform product, has been adopted in almost all breweries on the Continent, but it does not seem to have found favour with the English brewers at present.

It is true of all branches of manufacture that with the advance of science mere traditional methods must be given up or the manufacturer will stand no chance in the race. It is the stolid indifference to the teachings of science which places the English manufacturer so far behind his Continental competitors. The discovery of Dr. Hansen is of immense promise and commences a new era in the engineering of organisms for commercial purposes, and home manufacturers and producers would do well to study it. We should like to see bacteriology made a compulsory subject in the curriculum of certain branches of the engineering profession. We might then hope for a satisfactory solution of some of our knottiest sanitary problems.

History of the Cholera Controversy, with Directions for the Treatment of the Disease. By Sir GEORGE JOHNSON, M.D. Lond., F.R.C.P., F.R.S. London: J. & A. Churchill. 1896. Price 3*s*.

IT is a significant fact that the history of the progress of medicine might be built up from a series of controversies. No important statement or observation has ever been allowed to pass unchallenged, and those who have had the temerity to attempt innovations have had to be supported by the courage of their opinions against the clamour of negation or of militant doubt which, in medicine at least, seems always to be aroused when the old landmarks are moved. It is a sign of the vitality of thought that such opposition has never yet daunted those who felt they had a message to deliver, and without a doubt the opposition has in very many cases led to further experiments and further observations which have been of considerable value in strengthening the views originally advanced. Controversies are never pleasant, but they may be useful, and when sufficient time has elapsed for the fierce heat of contest to have cooled to a large extent they afford much instruction and also much encouragement. Investigation almost invariably shows that any fact which is "now admitted nearly on all sides" has had to run the gauntlet and that its author, instead of being at once lauded to the skies, has had to endure the disappointment of a sceptical or inimical reception of his discovery. Hence sympathy is evoked and comfort is derived. The book before us contains the history of a controversy around the question of the treatment of cholera. Sir George Johnson tells why he was dissatisfied with the results of treatment with brandy and opium so far back as 1849, and how in 1854 he had good opportunity of testing the effect of castor oil in cholera and choleraic diarrhœa and of the storm of opposition excited by the publication of his cases. This opposition must have been the more discouraging inasmuch as it was partly carried on within the walls of King's College Hospital, where the new treatment had already given excellent results. Sir George Johnson gives a vivid account of the reception of his views, and all who read will agree with the critic who found reason to respect the author for the courage and zeal with which he enunciated doctrines which he knew to be unpopular. Instead of being crushed by the opposition he was roused to further efforts and he eagerly called to his aid new physiological and pathological data which supported his views, and he was rewarded in 1866 by making a convert of Sir Thomas Watson, the President of the Royal College of Physicians of London. Sir George Johnson quotes largely from the various reviews which were written at the time and he triumphantly points to the recommendation of castor oil in the instructions drawn up in 1892 by the Royal College of Physicians of London at the request of the Local Government Board. The position held by Sir George Johnson is clearly stated here and emphasised by italics: "*Opiates are useful to soothe irritation after the evacuation of the bowel: they are useless and even dangerous when the blood is poisoned or the bowel filled with morbid secretions.*" It is difficult to put down this little book without referring once more to the date (1854) of the author's successful trial of the eliminative treatment and congratulating him upon the results of his labours and upon the clear and temperate tone with which they are described.

LIBRARY TABLE.

Aids to the Analysis of Food and Drugs. By T. H. PEARMAIN and C. G. MOOR, M.A., F.C.S. London: Baillière, Tindall, and Cox. 1895.—New analytical methods have to be devised from time to time to keep pace with the exceeding subtlety of modern adulteration. The Society of Public Analysts are doing excellent work in this direction, and

Digitized by Google

their publication, the *Analyst*, is a valuable record of recent processes connected with the detection of the adulteration of food and drugs. The work before us appears to be, so far as we have examined it, an admirable little digest of the analytical work required at the hands of the public analyst. The processes described have been pronounced reliable by well-known analytical practitioners. Though a small volume it covers the ground involved in the analysis of food and drugs, and it will be referred to with advantage by those who are familiar with laboratory work.

Professor Roentgen's "X" Rays and their Application in the New Photography. By AUGUST DITTMAR. London: Whittaker and Co.—The publication of *brochures* on the subject of the new photography supplies a distinct want now that everybody desires to know all about it. The one before us is a popular exposition by Mr. August Dittmar. It is a fair and correct review of the history of the subject, but gives very few practical details likely to be of service to the aspiring "new photographer."

Food Adulteration and its Detection. By JOHN A. BOWER. London: Society for Promoting Christian Knowledge. 1895.—In this little work are described some simple methods for the detection of food adulteration adapted to the capacity and resources of him who while running may read. So far it is of distinct educational value. But the author is now and again apt to lead the reader astray when he conveys the idea in some cases that the detection of adulteration is a simple matter. The microscope, for example, is recommended as a means of detecting foreign fats in butter, while the reader is recommended to ascertain the melting point by observing the point at which the fat clears, without taking the very necessary precaution of decanting the fat from the curd and salt and of filtering it. We doubt whether the fat would ever get clear under these circumstances. In the chapter on tea and coffee he counsels his readers to beware of coffee essences. We have found some very excellent preparations in the market, as a reference to THE LANCET of July 7th, 1894, will show. Speaking of aerated waters, he says "they should contain carbonic acid gas, but may contain merely compressed air"! The book will eagerly be read by the amateur analyst, and it will be his fault if he fails to understand the simply and intelligibly written chapters.

Kelly's London Medical Directory, 1896. London: Kelly and Co., Limited. 1896. Price 6*s*. 6*d*.—Hardly any publishers are more widely known and appreciated than Messrs. Kelly and Co., to whom Londoners are indebted for the bulky and indispensable Post-office Directory. Their Medical Directory is a convenient and well-executed volume of a little over 500 pages, giving the names, addresses, qualifications, appointments, writings, &c., of the medical and dental practitioners, male and female, in London and its vicinity. The area thus included extends from Hounslow on the west to Barking on the east, and from Croydon on the south to Barnet on the north. The streets list is sub-divided according to the postal districts, a refinement which is scarcely necessary. Much information is given relative to medical schools, hospitals, medical and learned societies, and the medical staffs of various departments of the public service.

Medical Notes and Statistics of the British Expedition to Egypt in 1801. By W. T. BLACK, F.R.C.S. Edin. Edinburgh: Oliver and Boyd. Pp. 12.—Mr. W. T. Black has published in a pamphlet form the substance of a lecture delivered by him some years ago before the Medico-Chirurgical Society of Edinburgh, and although the slender *brochure* bristles somewhat formidably with statistics, it contains much interesting matter, general as well as medical. The subject of Mr. Black's paper is the British Expedition to Egypt in 1801, when, in the words of Lockhart, "the victories of Abercrombie destroyed a fatal prejudice which had of recent days gained ground that the military of Great Britain were unfit to cope with those of revolutionary France. Sir Ralph Abercrombie fell, mortally wounded, in the moment of victory before Alexandria; but his successor, General Hutchinson (afterwards Earl of Donoughmore), assisted by Sir David Baird in command of the troops from India, proved himself thoroughly competent to replace the leader who, according to the same authority, "had the glory of first leading English soldiers to victory over the self-styled invincibles of Bonaparte."

JOURNALS AND REVIEWS.

The *Journal of State Medicine*, March, 1896. Vol. IV., No. 2. Price 2*s*.—This number contains papers of considerable interest, and amongst them may be mentioned one by Professor Delepine on the desirability of legislature in connexion with tuberculosis of living domestic animals. The author insists more particularly on the insufficient appreciation in practice of the powers of the bacillus tuberculosis to maintain a saprophytic existence and of the great prevalence of the disease among domestic animals. Dr. Sydney Marsden's paper on Municipal Abattoirs and Meat Inspection, which he read at the Hull Congress of the British Institute of Public Health, is reproduced, as also is the discussion to which it gave rise. An abstract of Mr. F. W. Richardson's paper on the Bacteriology of Water is also given, and in it Mr. Richardson discusses in an interesting manner what value is to be attached to the bacillus coli communis as an index of sewage pollution. We are also glad to see that the first report of the Public Health Committee of the General Medical Council on the Examinations in Sanitary Science is reproduced.

The *Sanitary Record*. Vol. XVII., No. 327. Price 3*d*.—This number contains an article on the Diagnosis of Enteric Fever by Dr. E. F. Willoughby, in which he gives a concise account of the varieties of the disease which may be met with in practice; but it seems to us that Dr. Willoughby hardly attaches sufficient importance to the spleen as an aid in the diagnosis of the disease. The answers to the last examination papers for inspectors of nuisances are furnished in the number before us; they should prove useful to those intending to enter for examination. A paper on the Multifarious Duties of the Medical Officer of Health for Sunderland should serve to warn candidates for public health appointments as to what is expected of them by some sanitary authorities, and the remuneration they are likely to obtain for their services.

The *Veterinary Journal and Annals of Comparative Pathology* for March contains an article on Immunity and Heredity, by Mr. M. H. Hayes, F.R.C.V.S., which is interesting from the fact that it shows from what point of view the veterinarian considers this subject. A translation of an article on a Case of Multiple Extra-uterine Gestation, with Osseous Embolism of the Pulmonary Artery, by Victor Drouin (Alfort), and articles on Subcutaneous Emphysema and Surra are also of interest. In the editorial department a somewhat stringent criticism of the report of the Board of Agriculture by Major Tennant, Principal of the Animals' Department, is given, from which it will be seen that the veterinary profession is by no means satisfied with the present arrangement at the Board, and there certainly seems reason to find fault with an arrangement which places in the hands of men who have had little or no veterinary training work which can only be carried out satisfactorily by experts. A rather personal controversy on the question of the educational examination for the veterinary profession is printed, from which it would appear that the Council of the Royal College of Veterinary Surgeons is making strenuous and necessary attempts to raise the standard of the

Digitized by Google

general education of candidates for its diploma. An interesting case of Tetanus in the Horse cured with Antitoxin is given. In the April number of the same journal there appears a further article on Immunity, read before the Edinburgh Veterinary Medical Society, in which the old question, so long debated by Buchner and others, concerning the possibility of the bacillus subtilis being converted into the bacillus anthracis is again raised, but this time in the form of the following statement: "In all probability the bacillus subtilis may be converted into the bacillus anthracis, and our principal (Williams) is of a strong belief that this can take place in a manure heap." The evidence of such conversion, it is to be feared, is not of a very clean-cut kind. The portion of Mr. Walter Long's Agricultural Bill which excludes the landing of Canadian and foreign store cattle does not receive much favour in the eyes of Scotch cattle-feeders, and for this several good reasons are given. Accounts of the proceedings of the various medical associations and abstracts and extracts from foreign journals, some of them of considerable general as well as veterinary interest, complete an interesting number.

The *Phonographic Quarterly Review*. April, 1896. London: Sir Isaac Pitman and Sons—The present issue is of more than ordinary interest to the medical man skilled in deciphering the "mystic" outlines of phonography, inasmuch as no less than four articles are contributed by members of our profession. Dr. J. A. Gray, late physician to H.H. the Amir of Afghanistan, whose graphic pen recorded his impressions of the Court at Cabul in our columns a short while ago, leads off with a well-written article on "Afghanistan, its Ruler and his Work." In it he ably endeavours to prove that the Amir is not so black as he is often painted, and shows that in spite of his apparent cruelty the ruler of Afghanistan is more humane than many Englishman are apt to think. "Jottings in a South African Village," by Mr. Herbert Caiger, F.R.C.S. Eng., is topical just now, but independently of this fact the paper will be perused with interest. In "The Great Emotion" (fear) Dr. Gowers has a subject which in his hands should be, as it is, ably treated. The article on the "Ways of a Wanderer," by Dr. G. E. Morrison, is continued, the thread of the author's autobiographical reminiscences being broken to admit of an editorial account of his walk across Australia. Of the other articles, not one of which deserves to be passed over, we have only space to mention Thomas Allen Reed's review of "Spencer's Lucid Shorthand." It is not generally known that the father of Mr. Herbert Spencer invented a system of shorthand which the well-known philosopher learned and used when a boy of thirteen. The system belongs to the class of "joined vowels," but otherwise does not show any great merit.

MAGAZINES.

Science Progress.—The April number of this publication is devoted very much to the evolution of ideas. The first paper is by Captain Creak, R.N., F.R.S., on the General Bearings of Magnetic Observations, in which we are again reminded of the valuable contributions to science afforded by the expedition of the *Challenger*. Dr. Starling writes (Part II.) on Some Applications of the Theory of Osmotic Pressures to Physiological Problems, and Professor Bourne contributes the first part of an article on the Present Position of Cell Theory. Histologists will read with interest the paper by Mr. A. G. Tansley, B.A., who gives the first part of a dissertation on the Stellar Theory: a History and a Criticism. "Solid Solutions" is the terse and apparently paradoxical heading of a paper by Dr. James Walker, who, we believe, succeeded Professor Percy Frankland in the chair of Chemistry in University College, Dundee. If solutions are defined as homogeneous mixtures of substances in variable proportions the above heading is justifiable, since there are many mixed solids which fulfil the requirements of this definition.

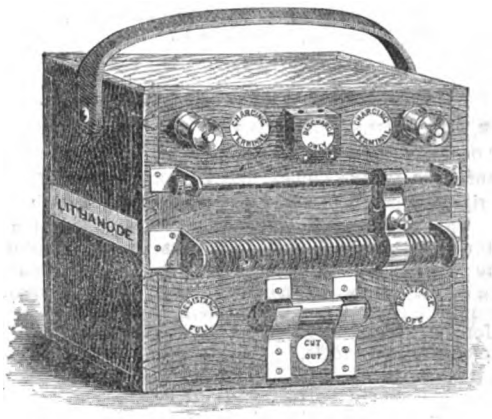
The Photogram.—This photographic monthly maintains its high artistic standard. It is printed on excellent paper and the reproduction of pictures is very well done. Considerable space is devoted to the "new photography," and the present number contains an excellent reproduction of a seven months' fœtus, which was the first complete human skeleton photographed by the new method. The original was by Professor Puluj of Prague.

New Inventions.

LITHANODE MEDICAL BATTERIES.

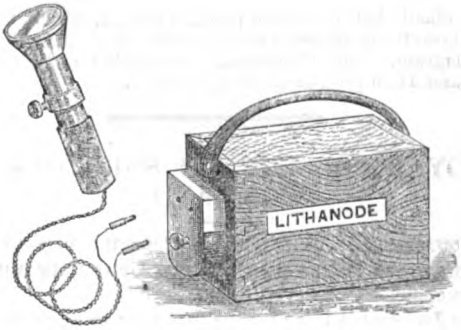
WE have recently had occasion to employ the Lithanode secondary batteries for working the induction coil for the new photography. For this purpose we have been using a two-cell 30-ampère hour battery identical with the battery shown in the illustration (Fig. 1), which is really constructed

FIG. 1.



for the purposes of an electro-cautery battery with a variable resistance capable of carrying current up to 20 ampères and fitted with a safety automatic cut-out. With an induction coil giving a three-inch spark discharge in air this battery worked admirably, and it could be readily replenished with current from the continuous supply main, using a lamp as resistance. For medical purposes it is extremely convenient and may be used for actuating large cauteries. Fig. 2 is described as the smallest and lightest

FIG. 2.

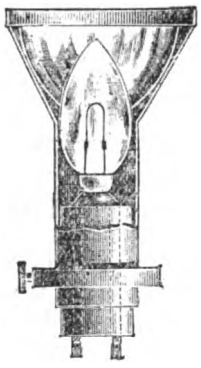


practicable secondary battery ever constructed, being 4⅜ in. long, 2 in. wide, and 3⅜ in. deep, and weighing only 1½ lb. Despite these small dimensions and light weight this battery is capable of working the search light shown in Fig. 3, which gives a projected light of as much as 20-candle power for a period of fully half an hour with one charge. We find

Digitized by Google

that the discharge of these batteries is admirably uniform and steady. As the name of these batteries implies, the anode plates are of a peculiar construction which offers distinct advantages. There is practically no limit to the

FIG. 3.



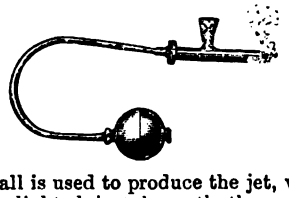
size of the lithanode batteries, which are eminently suitable for electric lighting, cautery work, and for driving motors. They save infinite trouble and inconvenience, and the makers recharge them for a moderate sum. They are made by the Lithanode Electric Storage Co., Ltd., 3, Harvey's-buildings (opposite Coutts' Bank), Strand, W.C.

ANTISEPTIC LIGATURES IN TUBES.

MR. JOHN MILNE, of Ladywell, S.E., sends us a specimen tube of his most recent method of packing ligatures. The ligatures are twelve inches long and are carefully attached to a rigid frame enclosed in a glass tube filled with carbolic oil. The advantages claimed by Mr. Milne for these ligatures in straight lengths are that there is absolutely no waste; that each length comes out in a straight thread, there being no corkscrew curl as from a reel; that no handling to take out the curl is required, it being simply drawn out with the forceps; and that it cannot possibly get out of order like those on revolving reels.

THE ZEPHYRON.

THE "Zephyron" is an invention by which the slow combustion of various vegetable cigarettes, such as stramonium, lobelia, and many others, is effected by the exhaustive action of a jet of air. The instrument is made of vulcanite, and a



small elastic ball is used to produce the jet, which acts when the cigarette is lighted just beneath the part marked × in the diagram. The "Zephyron" is supplied by Messrs. Maw, Son, and Thompson of Aldersgate-street.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on the 9th inst., the President, Mr. CHRISTOPHER HEATH, being in the chair.

The Jacksonian Prize for the past year was awarded to the author of the dissertation bearing the device of a photograph of a microscopic specimen, and the quotation:

> "What are these, so withered and so wild in their attire,
> That look not like the inhabitants o' the earth,
> And yet are on 't? —*Macbeth, Act I., Sc. 3.*

The President opened the sealed envelope and announced that Mr. A. A. Kanthack, F.R.C.S. Eng., was the Jacksonian prizeman. The subject for the Jacksonian prize for 1897 will be "The Pathology, Diagnosis, and Treatment of the various Neoplasms met with in the Stomach, Small Intestine, Cæcum, and Colon."

The Walker Prize of £60 was awarded to Mr. Harold Jalland Stiles, M.B., C.M., F.R.C.S. Edin. The committee appointed by the Council in pursuance of the declaration of trust for the administration of the Walker Prize Fund reported that they had duly taken into consideration the work done in the United Kingdom and elsewhere, either partially or wholly within the five years ending on Dec. 31st, 1895, in connexion with the advancement of the knowledge of pathology and therapeutics of cancer, but it became evident that in any report to be presented to the Council much important work could not be considered, either because (1) it had not been done within the prescribed time limit; (2) it had no direct bearing on the treatment of cancer; or (3) it dealt with matters still under discussion and did not admit of its value being as yet estimated by direct observation or experiment. Of what remained after elimination had been made on the above grounds the work done by Mr. Stiles appeared to be the most worthy of the prize, on the ground that he has investigated most minutely the morbid anatomy of cancer, its mode of spread, its relation to the organ in which it originates, and its relation to the lymphatic system of the part. His work on the pathological anatomy of the female breast and its accessory portions appears to be specially valuable from the fact that he has been able to demonstrate, by his nitric acid method, that the mammary acini have a much wider distribution than has hitherto been described. The importance of this in the determination of the extent of operative procedure is of course very great.

It was resolved that the Rush Medical College, Chicago, should be added to the list of foreign institutions recognised by the Examining Board for the complete course of study required by the regulations.

The report of the Laboratories' Committee showed that since the 6th December 3290 specimens of diphtheria material have been examined and reported upon for the Metropolitan Asylums Board, and that the director has during the same period supplied 2389 doses of antitoxic serum for the treatment of diphtheria in the hospitals of the board. In addition to the number of doses sent out, about 2500 doses, each containing 1000 Behring's normal immunisation-units, have been set aside, principally to meet extra calls should they arise. Two papers have already been published in connexion with the grant from the Goldsmiths' Company. Dr. Sidney Martin, in a preliminary communication published August 24th, 1895, gives the results of the action of the diphtheria antitoxin in neutralising the effects of the ferment toxine and albumoses formed during an attack of diphtheria. Dr. Cartwright Wood, in a recent communication to the Royal Society,[1] gave the result of his experiments on the rapid production of active diphtheria antitoxin. This part of the investigation is extremely important from the large quantities of antitoxin now employed. At first, by the ordinary method, and after a considerable time antitoxic serum of the strength of about 50 immunisation-units per cubic centimetre of serum was obtained. As the result of Dr. Wood's investigation serum has been obtained in nine weeks 1 cubic centimetre of which contains 250 immunisation-units, and in one month Dr. Wood was able to obtain serum of a strength such that 1 cubic centimetre contains 125 immunisation-units. As 4 cubic centimetres will contain 1000 units, the practice of subcutaneous injection, especially in the case of children, is rendered much easier.

The President reported that he had appointed Mr. Reginald Harrison and Mr. John Langton as delegates of the College to attend the celebration of the twenty-fifth anniversary of the German Surgical Society at Berlin.

The Council resolved that £510 should be invested out of the College funds and should be kept apart as the Arris Bequest.

In answer to a letter received from the Midwives Registration Association the Council resolved that they were not prepared to appoint a representative on a deputation to the Government.

A letter was read from Miss M. Edith Durham offering to the College a portrait by herself in low relief (bronze) of her father, the late Mr. Arthur E. Durham. The gift was accepted with the best thanks of the Council.

The next meeting of the Council will take place on May 14th.

THE LANCET.

LONDON: SATURDAY, APRIL 18, 1896.

SHOULD the next International Medical Congress prove to be a failure it will not be for want of examples to imitate or errors to avoid. The three last in the series of which it will be the twelfth—that at Rome, that at Berlin, and that in London—were, taken in reverse order, so many object-lessons by which its organisers may be expected to profit—Rome as a warning, Berlin as a *succès d'estime*, London as a model.

Perhaps the place at which it is to be held may be the means of saving it from what proved so disastrous to its Roman predecessor — the excessive number of the *congressisti*. Moscow cannot attract so many participants in its proceedings as did Rome. So hampered were the organising committee of the last Congress by the sheer weight of numbers that confusion invaded every detail of its programme and the result was, in the language of one of its most conspicuous promoters, "un fiasco solenne"—a monumental failure. Apart from the fascinating interest of the City of the Cæsars the Italians themselves were not blameless for the overcrowding that made the Congress so unfavourably memorable. They were, by their own subsequent admission, possessed by the record-breaking spirit and longed to excel their Northern and Western brethren in the magnitude of their medical parliament. The consequences, fraught as they were with disappointment and even bitter feeling, are too fresh in the memory to need recapitulation. Sufficient to say, that its most authoritative members, representing the leading European nationalities, were at one in thinking with the Italian promoter already cited that "beyond all dispute the Roman Congress registered the apogee of international congresses," and that "from this period onward we may anticipate a steady decline in their magnitude."

As with the number of participants, so with that of the papers sent in for discussion—the tendency of future congresses must be in the direction of curtailment, of concentration, and of economy in time and attention. A well-considered agenda paper, restricting the number of communications and rejecting all but those of supreme and present importance, must be the guiding principle of the next programme; while the sifting process that must precede it need not necessarily exclude from publication in a summarised form the thousand and one papers or monographs that are sure to be sent in. The whole system of International Congresses, indeed, is on its trial, and it will rest with the organising committee at Moscow whether the Congress now in preparation is, or is not, to mark a new departure in such professional gatherings in which the convenience and comfort of the participants are to be duly consulted with a vigilant and effective regard to the interests of science and the furtherance of enlightened practice.

We could suggest no better course for the organising committee than a re-perusal and consideration of Professor MICHAEL FOSTER'S paper at the last Congress on the Organisation of Science. Recommendations not more sagacious than practical were advanced in that masterly address which are as applicable to medical congresses as to medical literature—recommendations of which the root-idea is the inter-communication of workers in the same branch of inquiry, the comparison of results already achieved, and the avoidance of repetition of experiments already performed and of the re-traversing of ground already trodden. Preliminary correspondence with the heads of the leading medical schools throughout the world would put the committee in a position to know what each was working at and thought desirable, and from this knowledge to construct a programme which should minimise the number of themes to be taken up and reduce it still further by the exclusion of all that was of inferior scientific or clinical importance. Some such course, in fact, will have to be adopted if anything like cosmos is to replace the chaos which was all too present at the Eleventh Congress held at Rome.

The organising committee has already exhibited a very commendable readiness to listen to any reasonable protest, and this spirit together with the sensible determination to keep special subjects within proper limits and to avoid the excessive sub-division into sections which characterised former congresses promise well for the success of the meeting at Moscow. We have already commented favourably[1] on this action, and in the same article we took occasion to refer to the difficulties that were likely to arise in regard to the "official" languages in which the discussions were to be carried on. It will be remembered that the languages originally selected by the committee were French, Russian, and German. We pointed out that the exclusion of English would have "the effect of deterring large numbers, not only of Englishmen, but also of Canadians, Americans, Australians, and others" from attending the Congress or from sending papers to be read at it. Our protest was received in the friendly spirit in which it was made, and on April 4th we were glad to be able to publish the substance of a letter written by Professor ERISMAN, the General Secretary of the next International Congress, to our St. Petersburg correspondent to inform him that the question of languages is to be reconsidered by the executive committee, and that in all probability the English language will be admitted to equal rights with German, Russian, and French, and that "this will be done because it has become clear that the exclusion of the English language would not be well received by our English colleagues, and the committee do not consider themselves justified in insisting on their first decision if the general opinion of our English colleagues is clearly against it. You may rest assured that the committee, in discussing this question and coming to their first decision, were guided solely by considerations of what would be of advantage to the Congress and were far from having in view the national aspect of the matter." As we have said above, the whole system of International Congresses is on its trial, but we see no reason, if the organising committee and the Russian authorities generally continue to act in the same

[1] THE LANCET, March 14th, 1896, p. 719.

Digitized by Google

wise spirit of consideration and courtesy, why the Twelfth Congress should not be as successful as any of its predecessors.

DR. BATCHELOR'S address as president of the Fourth Inter-colonial Medical Congress of Australasia, which was published in THE LANCET of April 4th, 1896, possesses in some respects more general interest than usually attaches to such utterances. The subject was the Present and Prospective Conditions of Medical Education and the address may fairly be presumed to be a typical representation of professional opinion in our Australasian colonies on this important question. Many of Dr. BATCHELOR'S remarks are, no doubt, of quite general application and in no way coloured by local considerations, but it is always interesting to see the trend of opinion in our colonies, whether that opinion follows, or is in advance of, the views prevailing at home. Dr. BATCHELOR is of opinion that the amount of general culture required of the student before entering upon his medical curriculum is altogether insufficient and that the recent great advances both in primary and secondary education in England and the colonies would justify a much higher matriculation test than that commonly required. In this matter the University of London has set a notable example which has had, and will still have, far-reaching consequences. After matriculation Dr. BATCHELOR thinks that there "should ensue two years of special scientific subjects preparatory to the strict professional education, which should continue for at least four years further." This would, of course, involve a six years' curriculum, a reform for which we are not yet prepared, but which no one can pronounce either absurd or incapable of realisation in the perhaps distant future. As regards the subjects which should engage the student's attention at the stage preceding the strictly professional curriculum Dr. BATCHELOR says rather happily that "the medical man of the immediate future should, above all things, aim at being scientific in his habits of thought and methods of practice. He should have acquired the eye of science, the ear of science, the hand of science, the judgment of science; he should know that he really sees what he is looking at, hears what he is listening for, and touches with discrimination what he handles." This is undoubtedly the correct ideal, but opinions will differ as to how it may be most surely and adequately attained. The general feeling at present is strongly in favour of the view that this preliminary training is best afforded by the physical and biological sciences. We are not sure that this view, just as it probably is in the main, is not at present somewhat overpressed. Medical men have to do much more than observe, and the capacities that might constitute an admirable botanist or zoologist might make a poor physician. It is probable that the value of literature, of general culture, of a knowledge of "the best that has been thought and done in the world," of psychology, &c., will be more and more recognised as time goes on.

Dr. BATCHELOR is very strongly of opinion that it would be of no advantage to return to the old method of apprenticeship. This method, he thinks, once had its advantages. In former days "most work was empirical and it was surely of some advantage to be associated with an empiric of great experience and possibly considerable success. So much depended upon observation of more or less transitory significance that, in the absence of scientific or theoretical principles the methods of actual practice were doubtless as good as might be got. However, I am inclined to think that if anyone still advocates the old apprenticeship plan as suitable to modern requirements, such a man has allowed the tide to run past him; he has failed to note the signs of the times and does not observe that exact science has advanced, is advancing, and will continue to advance in every department of our work and that the need for increased opportunities for scientific training becomes for our junior students more and more impressive." This is a just and most important distinction. The old system of apprenticeship, while possessing some undeniable advantages, was apt to turn out clever empirics rather than thoroughly equipped scientific practitioners. Dr. BATCHELOR speaks approvingly of the medical curriculum of the University of Sydney, according to which, it would appear, the first two years of the student's course are devoted to chemistry, physics, anatomy, physiology, and biology, in the third year materia medica and therapeutics are introduced, and it is not until the fourth year that the purely professional subjects are begun. However excellent this may appear on paper we must point out a practical difficulty which seems to us to be a real one. A student cannot postpone the commencement of his hospital training to his fourth year, and all clinical teachers will agree that there is great inconvenience in carrying on clinical teaching with students who have had no systematic instruction in medicine and surgery. Dr. BATCHELOR pleads very earnestly for a closer and more sympathetic relationship between universities and colleges on the one hand and teaching hospitals on the other. On this point there will be a general acquiescence in the views which he puts forth.

We publish in other columns an extended although necessarily not an exhaustive account of the proceedings of the Congress, and we take the opportunity of congratulating our brethren "down below" generally, and the practitioners of New Zealand in particular, on the great success which has attended what was evidently a very useful and very pleasant gathering of the members of our profession in Australasia.

Floreant.

THE appeal of the Apothecaries' Hall of Ireland from the adverse judgment of the General Medical Council and its refusal to appoint examiners in surgery has an interest beyond that of the question immediately at issue. It is understood that the case between the society and the General Medical Council will be fixed for May, when the society will be represented by very able counsel and all that can be said in its favour will be advanced. Whatever the issue we cannot but regret that any such appeal should be necessary. The Medical Acts contemplate reference to the Privy Council in various emergencies. The Midwives Bill now before Parliament proposes to give a midwife whose name has been struck off the Register by the Midwives Board the right of appeal to the Privy Council. Could anything be more disproportionate or absurd? A practitioner removed

Digitized by Google

from the Medical Register has no such appeal. An appeal should be, if not easy, practicable and not far off; but an appeal from a midwife, say, in a provincial town, to the Privy Council is so impossible in aspect as to be tantamount to none. It is neither respectful to the midwife nor to the Privy Council. In plain terms it is ridiculous. It is creditable to the General Medical Council that this is the first time in its history that there has been an appeal from its judgment to that of the Privy Council. The General Medical Council is charged with the responsibility of representing the wisdom and justice of the whole profession in its relation to the public. There are two extremes of opinion which tend to bring about appeals to the Privy Council—that which regards the General Medical Council as existing only in the interest of the State and that which regards it as existing mainly to protect the interests of the profession. Both extremes are wrong. The General Medical Council is a domestic court to secure the efficiency and reputation of the medical profession partly through its corporations and other qualifying bodies and partly directly. Its powers are considerable, the more so as they are undefined. All who have the interest of the profession at heart will agree that the best thing for the profession is to have all questions arising under the Medical Acts settled in the General Medical Council. To have acted well nigh forty years without such an appeal being made to the Privy Council and also without any manifest disposition of the Privy Council to interfere with the action and freedom of the General Medical Council is some presumption that the latter body is capable of settling most questions. Those who think otherwise and who consider that some modification of its constitution is needed may well stay to consider the minimum of change required lest they compromise fatally the domesticity of the government of the profession.

Annotations.

"Ne quid nimis."

A CENTRAL BOARD FOR HOSPITALS.

THERE was a good meeting in the theatre of the Royal United Service Institution, Whitehall, on the 13th inst., to hear the scheme of the Charity Organisation Society, though many presumable supporters of the scheme were unable to be present. The scheme would give a place on the Board of 169 to about thirteen classes of representatives. The list of institutions or interests to be represented is a formidable one:—General hospitals, special hospitals, medical schools, provident dispensaries, other medical charities, medical corporations, the London County Council, the British Medical Association, the Hospital Sunday Fund, the Hospital Saturday Fund, the Charity Organisation Society, the City Parochial Foundation, and general practitioners. It requires a considerable stretch of imagination to suppose that charitable institutions maintained by voluntary subscriptions will consent to be controlled by bodies that do not subscribe to their maintenance and to which they owe no allegiance. Why should they invite the intrusion of the London County Council? or upon what theory is the British Medical Association to interfere? The best chance of success will lie in seeking, at least in the first instance, the coöperation of representatives of every existing charity that commands the respect of the public and of the Hospital Sunday and Saturday Funds. Mr. Sydney Holland is not far wrong in arguing that only some body that is supported by the power of the purse will have much controlling influence. The claim of the Charity Organisation Society to be represented may be disputed, but the hospitals would do well to recognise it. It may seem more critical than sympathetic sometimes, but its benevolence cannot be doubted, and hospitals would be stronger in public estimation for listening a little more to some of its criticisms. We repeat that a more modest beginning of a board should be attempted. Once established and worked, as Mr. Brudenell Carter suggests, "by advice, conciliation, and reasoning," it may do much good; it can easily be enlarged by the addition of the representative of any class or interest that gives substantial proof of its sympathy. This subject will be discussed by the Hospitals Association at the board room, Charing-cross Hospital, on Thursday, April 23rd, at 8 P.M. Lord Monkswell, a member of the Select Committee of the House of Lords on Hospitals, will preside, and important resolutions will be moved in favour of a reconstitution of the Distribution Committee of the Hospital Sunday Fund and of a central board of supervision.

THE NEW PHOTOGRAPHY: A STEP FORWARD.

WE have this week received information of a development in the new photographic process which promises to be of great importance in regard to its application to medicine. The improvement consists essentially in very materially reducing the exposure, so that in the case of hands and feet, &c. a few seconds suffice to give satisfactory detail. We have seen some good negatives so obtained with an exposure of less than twenty seconds. The process is occupying the attention of our laboratory department, but in the meantime it may be stated that the results are obtained by placing the negative (film side) upon powdered fluor-spar. It is evident in this case that the active rays are transmitted through the glass. The process gives promise of enabling us to obtain photographic images of objects within the human body with a comparatively short exposure, say five to ten minutes. The procedure would appear to be simple, and we hope many investigators will be induced to try it as it is in the direction of reduced exposure that progress is most needed to make Professor Roentgen's discovery of real value in medicine.

Mr. Nikola Tesla has made public the results of some of his experiments. He has worked, as might be expected, chiefly with the disruptive discharge coil commonly known by his name. He has obtained photographic impressions at distances of forty feet from the tube, and his first communication gives a large photograph of a person's back, showing the humerus and scapula. In the second letter he complains that the picture had suffered much in reproduction and that it ought to have shown clear indications of the ribs. He prefers a vacuum tube having one pole only; he insists that the higher the potential the greater the effect, and speaks of a luminous atmosphere as surrounding the vacuum tube while it is in action. From this and other points we are led to believe that he makes use of enormous potentials. In this country the Tesla coil has been regarded as less useful than the Ruhmkorff for "x" ray purposes, the powerful effect of the former upon the vacuum tubes being considered a disadvantage. Certain experimenters in London have obtained results from the use of a Tesla coil with the lamp attached to a single pole. Tesla's first paper, in the *American Electrical Review* of March 11th, is valuable because it describes the phenomena occurring in the vacuum tube, and enables an operator to see when the tube is

Digitized by Google

working at its best effect. He expresses the opinion that there is an actual passage of molecules from the interior of the tube to the outside, and thinks the sensitive plate is actually "bombarded" by these molecules; he also gives his reasons for this belief.

A JUDGE ON VACCINATION.

SIR WILLIAM GRANTHAM is chairman of the Barcombe parish council—Barcombe is a small village in Sussex—and at the close of the meeting of that body the other evening he took occasion to make a few remarks on vaccination, referring especially to the removal of the last assize from Gloucester to Cheltenham. A man who had been working in the assize court had, he said, been suffering from the disease of small-pox, and the Sheriff and Under-Sheriff consulted him as to the advisability of closing the public galleries. Holding this to be a serious step, he said he thought that it would be much better to remove the assize altogether, and as fortunately the city had no voice in the matter he, through the Lord Chancellor, obtained the necessary order of the Privy Council to take the assize to any place he might name, and he chose Cheltenham as the nearest place. To show that it was not from any personal fear, added Sir William Grantham, he went to Gloucester to try certain cases which had to be taken by a city jury, and also attended service in the cathedral. He referred to the protests of the anti-vaccinationists, and remarked that there were people in Gloucester who said boldly and publicly that they would rather see their children dead in their coffins than see them vaccinated. He was sorry to say they had been rewarded in the way they wanted; their children had died, but their conduct had created a spirit of lawlessness that perhaps they did not anticipate. Sir William Grantham went on to explain very lucidly the use of vaccine as a prophylactic, quoting extensive figures, and it is hardly necessary to state that the local and the executive anti-vaccinationist has come down like a wolf on the fold with an array of figures in opposition. Locally the speech has attracted much attention and some criticism, but his colleagues on the council passed a vote of thanks to Sir William Grantham for his useful speech.

IL CONTE MATTEI.

OUR Rome correspondent writes: Of the myriads of railway passengers who annually thread the many tunnels between Bologna and Florence how few are aware that not far from the station of Vergato stands the "Castello dei Miracoli," the picturesque abode of the most prosperous irregular practitioner of the nineteenth century. There it was that Count Mattei, scion of a rich and noble Genoese family, lived and laboured; there he received pilgrims for whom he was the embodiment of Bacon's "nobilis in villula lucubrans"—the patrician grappling with Nature in his château. There he sat as the central spider of a web whose ramifications extended all the world over and enmeshed patients of high and low degree, especially the former. Statesmen and diplomatists, men to whose judgment and finesse the most momentous as well as the most delicate missions were confided, had no hesitation in entrusting their health, mental and bodily, to a man who, according to his latest panegyrist, "studiò da se la medicina dopo avere scoperto il suo grande segreto" (studied medicine by himself after—note the order—after having discovered his great secret). And they were quite ready to show cause for the faith that was in them and one and all to assure their hearers that, having found orthodox medicine useless or worse, they had got rid of their ailment (whatever it was) and regained their powers of work and enjoyment of life by Count Mattei's "granellini di zucchero saturi di elettricità bianca, bleu, rossa, o verde" (sugar granules charged with white, blue, red, or green electricity), which were equally good for tubercle or chilblains, anæmia or plethora, cancer or wry-neck, acute melancholia or inhibitory paresis. The infallible logic of *post hoc, ergo propter hoc* was, in the case of these masters of statecraft, weapon sufficient to discomfit all sceptics as to the reality of their cure. Science and research demurred in vain to a remedy which was alleged to be equally efficacious in maladies not only contrary but antagonistic, while all the time, under the shelter of social prestige and aristocratic testimony, Count Mattei was not merely adding daily to his "miraculous cures" but steadily amassing a fortune which, in the language of the panegyrist aforesaid, "lo fece più volte millionario" (made him several times over a millionaire). Vainly did foreign custom-houses interpose their barrier to the import of his "granellini." Vainly was the law invoked against the sale of patent medicines the composition of which was undeclared even to the licensing authority. "Agents" were found not only to introduce the granules into every Christian country, but to effect their sale in quarters the most conspicuous and exposed, and the army of such functionaries, subsidised by Count Mattei at considerable cost, still left the gains from the "business" enormous. Dying the other day at Bologna he has bequeathed two million lire (£80,000) to charities, while the bulk of his fortune descends to his adopted son and heir, Mario Venturoli Mattei, to whom he has also left his "segreto miracoloso."

THE MANUFACTURE OF ARSENICAL SHEEP DIPS.

A FEW months ago some sensational revelations concerning the disastrous effects of the making of poisonous sheep dips on the operatives of certain East-end factories were published in an East-end paper. Assuming that these allegations had some foundation in fact we commented on the subject and emphasised the necessity of the Government taking instant measures to protect persons engaged in such an apparently dangerous employment. On the face of it it is reasonable to suppose that the preparation of a mixture containing nearly 20 per cent. of such a highly poisonous substance as white arsenic would be attended with some risk to health. We have, however, recently been convinced that it is quite possible to reduce the conditions of danger practically to *nil* by taking certain precautions in every stage of the manufacture. Our attention was directed to this fact by Messrs. William Cooper and Nephews, whose factory at Berkhamsted we recently inspected. We were much struck by the extremely healthy appearance of all those employed in and about the works. Most factory hands look pale and pasty, but all the men and boys we saw—and we visited all the shops—were ruddy, clean-skinned, and clear eyed. Sulphide of arsenic, which is to some extent formed during the course of manufacture, is very insoluble, and there is only one man in the place who has anything to do with the raw arsenious acid. He had been employed for thirty-three years, so that even working with the drug in a more easily assimilable form than the sulphide seemed to have had little or no effect upon him. This speaks volumes when we consider the fact also as some indication of the extent of the manufacture that the sale of this dip in 1895 was in excess of 1894 by over a million packets, representing an increased output of over 800 tons in one year. The only chance of risk appears to us to be involved not in the processes of actual manufacture in these particular works, but in the measuring out of the product into the cardboard packets. But in this department, also, every precaution that can be taken is adopted. The risk, however, attending this department will shortly be removed since we saw a highly ingenious piece of machinery being erected for the automatic measurement and for the packing of the powder. We record with

Digitized by Google

pleasure the care which is taken at these large and typical works to provide against injury to the workmen. We hope that the committee now sitting and inquiring into dangerous trades will compel similar precautionary measures to be adopted in all other factories where risks of the same kind exist. The application of arsenic for sheep dipping purposes would appear to require some care, but in the proportion that the arsenical compound is dissolved in water for the preparation of the dip it is quite safe. This is evident from the fact that 125 million sheep were dipped in a solution of the powder referred to without a single accident.

THE ARRIS AND GALE LECTURES.

IT appears that the lecturers paid by the Royal College of Surgeons of England out of the Arris and Gale bequests have hitherto only received the Gale portion of the remuneration. The Arris portion had by mistake become engulphed in the general coffers of the College. This is to be put right, and the sum of £510 is to be invested out of the College funds and set apart to fulfil the purposes of the bequest.

THE GENERAL HOSPITAL, ADELAIDE, SOUTH AUSTRALIA: A WARNING.

WE regret to learn from a telegram received on the 15th inst. by the President of the Medical Defence Union, that a very serious difficulty has arisen at Adelaide. The terms of the telegram are as follows: "Adelaide, April 15th, 1896. Government propose import paid men to replace Adelaide Hospital honorary staff, who have resigned in body under protest against Government action. Profession support them. Inform medical papers. Further particulars later." From the foregoing it is at least evident that no medical practitioner should accept any appointment to the Adelaide Hospital that may be offered him by the South Australian Government in the absence of the further information which has been promised. Immediately on receipt of this we will publish a statement of the causes which have led to this regrettable state of things.

EXTRAORDINARY TREATMENT OF AN EDINBURGH MEDICAL MAN.

A FEW weeks ago a paragraph appeared in the newspapers stating that, as the result of a post-mortem examination of a girl's body, an Edinburgh practitioner, Mr. G. M. Stocks, L.R.C.P., L.R.C.S. Edin., had been arrested on a charge of murder for performing an illegal operation from which death resulted. It appears that he was treated like a common felon, being taken from the court-house to the prison handcuffed to pickpockets. After a time he was released on bail, and now he has been released altogether, the authorities having decided that there is no case against him. We hope next week to give the declaration made by Mr. Stocks to the Sheriff, from which it will be seen that a most extraordinary blunder has been made and that a hideous wrong has been done to an innocent member of the profession. The fact that the authorities have had to abandon all further proceedings is sufficient evidence of that fact. Unfortunately, there is no redress from Crown servants protected by privilege, and investigations conducted by the public prosecutor are made in private; but the profession is fully entitled to ask on what class of evidence was the warrant for the apprehension issued, or was it, as stated in the public press, the result of a post-mortem examination or the result of police inquiries? This point is, of course, one about which there ought to be no difficulty in ascertaining the truth. To the profession as a whole the case is of great importance and gravity, for it means that a medical man in the performance of his usual professional work may be suddenly arrested on the gravest of charges, and yet his arrest be due either to an opinion so erroneous or so distorted (in spite of a post-mortem examination) or to other evidence so flimsy that the charge collapses as soon as the competent authorities look into it. This cannot be regarded as a satisfactory possibility, and when it has been ascertained upon whose shoulders the blame rests it is to be hoped that steps may be taken to prevent the possibility of similar mistakes in the same quarter.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.

THE annual meeting of the London and Counties Medical Protection Society, Limited, will be held on Friday, May 1st, 1896, at the Restaurant Frascati, Oxford-street, London, at 5 P.M. The annual dinner of the Society will take place after the meeting at 7 P.M., under the presidency of Mr. Hutchinson, F.R.S. Medical men, not members of the Society, but interested in its work, are cordially invited to attend the dinner. Tickets, price 7*s.* 6*d.* each, exclusive of wine, may be had on application to the secretary, Dr. Hugh Woods, 11, Archway-road, Highgate, London, N.

THE RECENT CASE OF POISONING BY ANTITOXIC SERUM.

IT is perhaps one of the greatest tributes that the success of the antitoxic serum treatment could have paid to it that such widespread anxiety should be evinced at the recent case of alleged poisoning through its use that has occurred in Berlin. As yet it is not advisable to express any definite opinion on this case, but it may be well, whilst reserving judgment, to point out that the reports hitherto received and promptly transmitted to the public press are of a very vague and unsatisfactory character. First, it was stated that the child died several hours after the injection had been made; then news was sent that death took place within a few minutes of the injection. Now with the exception of the most virulent poisons death in such a short period is seldom brought about. In this instance it may be assumed that similar serum had been supplied for use on other patients, and had there been a poison virulent enough to cause the death of the patient in such a short time reports of other deaths must ere this have been received. It is satisfactory to learn that a careful analysis of the serum, which was sealed up immediately after this unfortunate occurrence, will be made, for there can be little doubt that this case will be made a centre around which will be grouped all the ill effects that follow the use of serum, whether *post hoc* or *propter hoc*, in any case of diphtheria.

THE RIGHTS OF THE SUBSCRIBER.

WE learn from a letter by Dr. Lediard, published recently in the *Carlisle Patriot*, that there is a proposal on foot to make some radical alterations in the voting powers of the subscribers to the Cumberland Infirmary. As matters now stand it is laid down by the statutes of this institution that: "Every subscriber of 2 guineas annually and every benefactor of 20 guineas shall have one vote at election of officers; every subscriber of 5 guineas annually and every benefactor of 50 guineas shall have two votes; every subscriber of 10 guineas or upwards annually and every benefactor of 100 guineas or upwards shall have three votes." It is now proposed that this elective power should be taken away from each individual subscriber and be put into the hands of a committee to be appointed triennially for the purpose. We must say that on the whole we sympathise with the proposed change and believe that in the end the institution in question would benefit by it. One objection

Digitized by Google

put forth against it is the possibility of a falling off in the number of subscriptions, the idea being that by having direct votes the subscribers feel they are "getting something for their money." We do not think the desire for votes will be likely to make much difference, besides which they will still have the privilege of electing their representatives on the committee. Looking at it from the honorary officers' point of view, we can only think the change would be a healthy one. Canvassing the county to obtain an honorary post on a hospital staff cannot but be a most objectionable proceeding to all concerned, and only naturally in such cases personal considerations are often apt to outweigh all others in the voting. By all means let each subscriber have a voice in the election of the committee, but the committee should do the electing. This would be a far less cumbersome method of proceeding than the one in vogue and one which should result in putting the right man in the right place.

MACCLESFIELD INFIRMARY.

MYSTERIOUS disappearances of important documents are a staple theme for elaboration by writers of fiction, and they occasionally occur in real life, with the result of producing much trouble and anxiety as well as sometimes a gratifying field of operations for the legal profession. The authorities of Macclesfield Infirmary are at present much perplexed by their inability to lay hands on the trust deed of the institution—an undesirable predicament for a public body to be in, although not likely to be attended by any awkward consequences. The honorary secretary has not seen the document since December, 1858, when it was completed and handed over to the residuary owner of the trust fund in the event of the trust relating to the infirmary failing from any cause. The gentleman into whose keeping it then passed had the custody of the documents and securities of Mr. Tunnicliffe, the founder of the infirmary, and he transferred the endowment fund to the Corporation of Macclesfield in compliance with the trust deed. The infirmary was opened in October, 1872, the proceedings were recorded in the *Macclesfield Courier and Herald* at the time, and the conductors of that prosperous journal have now the satisfaction of knowing that its columns contain the only available transcript of the missing document. It was supposed to be deposited in the safe of the Macclesfield Corporation, and the search for it appears to be conducted with such lack of zeal that when a meeting of the Documents Committee was summoned to investigate the matter only one gentleman was in attendance.

IMPROVEMENTS IN BRITISH BALNEOLOGICAL PRACTICE.

A SATISFACTORY feature in the recent history of British medicine has been the re-organisation of some of our most important spas and watering-places, and the serious attempt made to put this important department of practice on a scientific basis. Mr. Douglas Kerr's recent paper at the Balneological and Climatological Society draws attention afresh to this subject. Bath has in recent years quite renewed its ancient glory, while Harrogate, Buxton, and Droitwich—to mention a few out of many—are now among the best-equipped sanatoria in the world. Certain advantages, indeed, our continental rivals will continue to possess over us. No British resort can compete in point of climate with Carlsbad or Homburg or Vichy. In the matter of amusements also, especially in the provision of really high-class music, the continental spas are still superior to our own, though great progress has undoubtedly been made in this particular at the home resorts. It is well to remember that the patients who chiefly frequent these resorts are seldom complete invalids, that exercise in the fresh air is usually a cardinal principle of treatment, and that hence amusements of the right kind and of good quality are indispensable. The foreign resorts seem to excel in ingenious methods of applying the different waters. The Mont Dore methods are well known and are now imitated at several of the home resorts. The most recent innovation of this kind is the Nauheim treatment of chronic cardiac disease. The speakers at the recent discussion at the Balneological and Climatological Society seemed much divided regarding the methods of the new treatment. Mr. Holbeche of Malvern could not fully understand the *rationale* of the treatment. Dr. Snow thought the facts at present before the profession were insufficient to warrant any positive conclusion. Dr. Sunderland thought that the Nauheim treatment had been generally accepted on as slender evidence as the Koch cure for tuberculosis had been accepted a few years ago. Mr. Shirley Jones of Droitwich had tried the treatment with somewhat ambiguous results. It is evident that the Nauheim therapy is at present largely engaging the attention of the profession, and further information and evidence on the subject will be awaited with much interest. The facts hitherto educed, however striking and suggestive, have not been sufficient to carry general conviction.

THE RELATION OF DISEASES OF FOWLS TO DIPHTHERIA.

M. GALLEZ *fils*, who has been investigating the relation of diphtheria to the diseases of birds, has reported to the Belgian Academy of Medicine that there are two perfectly distinct diseases to which such birds as domestic fowls are subject. First, a contagious catarrh called also *morve* or "fowl glanders," characterised by a glairy secretion from the mucous membrane of the mouth, nostrils, and eyes, and also by rapid emaciation and paralysis of the legs. It is very contagious and very fatal, and may give rise to diphtheria in the human subject. Its primary cause is a bacillus similar to Löffler's, but far less virulent. If its virulence is artificially increased and a large dose injected into a dog or a guinea-pig, say ten cubic centimetres per kilogramme of the animal's weight, death rapidly ensues with symptoms precisely similar to those induced by Löffler's bacillus. When injected into fowls the so-called *morve* is reproduced. This disease differs from the second one, which is known as "fowl diphtheria," both in its symptoms and in its etiology, but has nothing corresponding to human diphtheria except its name. Experiments with antidiphtheritic serum showed that some curative effect was produced in fowls suffering from "contagious catarrh," though M. Gallez is unable to affirm that it acts as a certain specific. He explains the frequent immunity of persons handling fowls suffering from "contagious catarrh" to the comparatively slight virulence of the bacillus concerned as compared with that of the true Löffler's bacillus.

PEMPHIGUS.

DERMATOLOGISTS have generally regarded as typical cases of pemphigus that condition described by Duhring as dermatitis herpetiformis and also include under the same term urticaria papulo-bullosa, erythema multiforme, pustulous dermatitis, and hydroa. In the *Monatshefte für Praktische Dermatologie*, Band xxii., No. 6, is a short paper by Professor Petrini di Galatz of Bucharest. He comments on the various forms of skin disease which have been described under the term "pemphigus" and enumerates several in addition to those named above. He describes three varieties of pemphigus: (1) pemphigus vulgaris chronicus with periodic exacerbations and generally fatal termination; (2) pemphigus foliaceus; and (3) pemphigus vegetans vulgaris. The two latter forms may commence as a pemphigus vulgaris chronicus

Digitized by Google

(type 1), and then pass into either of the two other types. The last variety leads to a severe cachexia; it is the rarest of the three and the most dangerous. Closely resembling these three types of the disease is another condition which Professor Galatz draws attention to—namely, a group of "bullous dermatoses" which has been described as "pemphigus benignus," and which occurs in young subjects and is very apt to recur once or twice, but always ends in recovery. Bazin has described this same condition under the term of "hydroa bullosa," and it has sometimes been termed simply "hydroa," but it is not the same disease to which English dermatologists apply the term. But Professor Galatz thinks it very unadvisable to include under the term "pemphigus" bullous eruptions which in the course of two or three weeks quite disappear when the true pemphigus is such a serious and often fatal disease. According to his opinion pemphigus is the most serious of all dermatoses and yields the highest mortality, whilst "hydroa" (in the sense described above) is one of the least dangerous. The condition known as "pemphigus circinatus" he does not include as a true pemphigus, but includes it under the heading of Duhring's dermatitis, together with herpes iris, erythema iris, and erythema bullosum.

THE WATER-SUPPLY OF EGYPT.

IN his recent report Lord Cromer draws attention to a discovery which, he thinks, may revolutionise the whole question of the provincial water-supply in Egypt. In the opinion of our Consul-General in Egypt, "the importance of this discovery cannot be overrated. As the construction of filter-beds forms one of the heaviest items of expenditure in connexion with the water-supply of a town, and as it has been this particular initial outlay which has rendered the profits of these undertakings doubtful, it is evident that if a supply of pure water can be obtained by the comparatively cheap method described above it should not be difficult to attract capital into similar enterprises with a reasonable prospect of a return for the money sunk. As the geological formation of the Delta may be presumed not to vary greatly it is reasonable to suppose that the question of a good water-supply for the towns lying in this part of Egypt has been brought within the limits of practical solution." Borings recently undertaken at Tantah, in the centre of the Delta, prove that beneath the external alluvial deposit and the sand underlying it a second and apparently impermeable bed of clay exists at a depth of about 69 ft. from the surface. The thickness of this deep-seated bed is 6¾ ft., and as soon as the boring-tube pierced it water rose to within a yard of the ground level. The tube was then made to descend a further distance of 37 ft. through sand, the total depth attained being thus 106 ft. The supply of water is described as inexhaustible and apparently of the purest quality. Samples have been submitted for bacteriological examination to the Government expert, and if his report is favourable a firm of contractors is to be authorised to sink a well for the supply of the town. It has long been known that water could be obtained pretty nearly anywhere in Lower Egypt, provided the borings were carried deep enough, but apparently the idea of making use of it in the manner indicated by Lord Cromer never before occurred to anyone in authority. Some years ago the Royal Engineers took experimental soundings, so to speak, at Zagazig; and at Mena House, near the Giseh Pyramids, what has been called an artesian well exists furnishing an ample supply of extremely pure water. Specimens of the latter have been frequently analysed and pronounced to be practically identical with Nile water, and no doubt a similar result will attend the investigation now pending. That any water save Nile water should exist towards the sea end of the Nile valley appears to us extremely improbable. No doubt the water permeates the bed of the river at countless points in its downward course and then makes its way to the Delta beneath the impermeable clay stratum. If this explanation be correct there may be said to be two or more Niles constantly flowing seawards and superimposed one above the other. In this connexion we would draw the attention of the Egyptian authorities to the advisability of providing drainage for the removal, after fouling, of the water it is their intention to furnish. An unlimited supply of water in a town where there are no sewers is by no means an unmixed blessing. In an appendix to Lord Cromer's report Mr. Garstin insists on the necessity of drainage for agricultural purposes. The head of the irrigation department calls it "one of the most crying wants of Egypt at present," but to our minds the total absence of all drainage in the towns, from Cairo downwards, is a still more crying evil. In one case the increase of revenue is concerned, in the other the lives of thousands are at stake.

THE REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA.

WE do not propose to deal with this voluminous and very able report on the present occasion, but we may nevertheless allude very briefly to the section devoted to the European Army of India during 1894. The year, we are told, having been a very wet one over the greater part of India, especially of Northern India, sickness increased, and influenza, cholera, and malarial fevers were more prevalent than in 1893. The strength of the European troops in the country was 71,082 in 1894; the admission-, constantly sick-, and death-rates were all higher than in the preceding year; the death-rate was 16·07 per 1000, whereas in 1893 it was only 12·61. The chief causes of mortality were enteric fever, cholera, hepatic abscess, and injuries. Enteric fever caused 36 per cent. of the total deaths and cholera 13 per cent. Among the diseases which caused increased admission rates were influenza, cholera, enteric fever, ague, respiratory disease, dysentery, and venereal diseases — the latter caused no less than 34 per cent. of the total sickness and ague 26 per cent. In all the three presidencies venereal diseases and ague head the list of admissions into hospital. As regards mortality, however, enteric fever heads the list in all three presidencies, and in Bengal and Bombay the ratio was higher than the average of the decennium. We hope shortly to deal more fully with the report of the Sanitary Commissioner with the Government of India, but the foregoing figures will suffice to show the grave importance of the increasing prevalence of certain diseases among our troops serving in India.

CENTRAL CHANGES IN PERIPHERAL NEURITIS.

IN a recent number of the *Archives of Neurologie* Dr. Soukhanoff has an article on this subject, with special reference to a case of which he furnishes particulars. Until a short time ago peripheral neuritis was supposed to be a disease in which the lesion was confined to the peripheral nerves, but Kahler and Pick, Korsakow, Eichhorst, Campbell, and others have shown that changes also take place in the spinal cord, especially in the columns of Goll, although changes in the ganglion cells have also been described. Dr. Soukhanoff's case was that of a patient twenty-one years of age with a family history in which there were traces of a neurotic taint. He was of an amiable but somewhat weak character, often showed considerable energy, but never for very long at a time, was easily tired, and very impressionable. He developed a tendency to indulgence in alcohol, not a craving, but in his case sufficiently strong to lead to considerable over-indulgence. In 1892 he had an attack of delirium tremens and another in 1894. In

Digitized by Google

the latter he threw himself out of a second storey window. A few months before his admission to hospital he was noticed to walk feebly and he was much troubled with stomach derangement. He gradually became worse, and on his admission there were slight weakness of the right side of the face, nystagmus, feebleness of both arms but more of the right than of the left, the hands being weaker than the other parts of the limbs, and there was also weakness in both legs, but affecting the smaller muscles most. The knee-jerks were not obtained and there was tenderness on pressure. The memory was bad and there was considerable psychical change. Tubercle bacilli were present in his sputum and he gradually became more and more feeble, the immediate cause of death being the pulmonary condition. At the necropsy empyema and advanced phthisical processes were found in the lungs and parenchymatous neuritis in the peripheral nerves. But changes were also found in the cord, the columns of Goll in particular being degenerated throughout almost the whole extent of the cord.

THE CHEMISTRY OF THE POISONS OF DIPHTHERIA.

WE have noted in our report of the proceedings of the last meeting of the Council of the Royal College of Surgeons of England that Dr. Sidney Martin has laid before the College a preliminary report of the work done by him in connexion with this subject under the grant from the Goldsmiths' Company. It appears to us that Dr. Sidney Martin's work is very suggestive, and a further report in confirmation will be awaited with interest. He has ascertained that the antitoxin, when injected by itself, in no way interferes with the nutrition of the animal, the temperature remaining normal and the weight increasing steadily. When injected along with the ferment toxine it prevents any marked rise of temperature, allows the weight to rise, and if given in sufficient quantities prevents degenerative changes of the nerves and cardiac muscle, although, if the quantity of antitoxin be not sufficient, some slight degeneration of nerves is noticeable. When injected along with the albumose, which by itself causes marked fever with first a rise and then a fall of temperature, the febrile reaction is greatly modified. The temperature varies much less than when the albumose is given alone and rapidly returns to the normal. As regards alteration in weight—an important indication of the state of nutrition—the albumose alone appears somewhat to interfere with natural increase, though it seldom determines any diminution, but when it is mixed with antitoxin the weight of the animal steadily and rapidly increases. Albumose alone produces degeneration of both nerves and muscles, and its exhibition is frequently followed by paralysis; but when antitoxin is given along with it these conditions do not make their appearance. Dr. Martin is continuing his investigations. Two important points brought out by his recent experiments are: (1) that antitoxin, if properly prepared, is harmless when tested on animals; and (2) that in the case of patients suffering from severe diphtheria it is necessary to give much larger doses than in ordinary cases (4000 immunisation-units) in order to neutralise the action of ferment-toxines and albumoses.

A PAPER of great importance to sanitary authorities was read by Dr. John F. J. Sykes, medical officer of health of St. Pancras, before a meeting of the Sanitary Institute on Wednesday last. The almost hopeless tangle (caused by cross-references) in which the Factory and Workshop Acts are at present makes a *précis* of the Acts set out in logical order of the utmost value, and this Dr. Sykes attempted to do. We hope to print a summary of the paper in a future issue of THE LANCET.

THE Hunterian Society proposes, on Wednesday, April 22nd, at 8 30 P.M., at the London Institution, Finsbury-circus, to hold a discussion on Joint Affections in Nervous Diseases. Mr. Targett will read a short paper on the subject illustrated by lantern slides. Dr. Beevor, Dr. Buzzard, Dr. W. M. Ord, and Dr. Aldren Turner have promised to take part in the discussion. Visitors will be cordially welcomed, and any wishing to speak are requested to communicate with the senior honorary secretary, Dr. F. J. Smith, 4, Christopher-street, E.C.

WE have received from the Home Department a programme of the Second International Pharmaceutical Exhibition which has reached that department from Austria through the Foreign Office. The exhibition will be held in Prague from Aug. 15th to Sept. 15th, 1896, and the executive committee invites exhibitors. All communications should be made to the President of the Executive Committee, Dr. K. Fragner, Prague, who will give information in answer to inquiries.

A CONFERENCE on the subject of Irish Workhouse Reform is to be held at St. Martin's Town Hall, Charing-cross, on Wednesday, April 29th, at 3 P.M., at which Dr. Moorhead, honorary secretary of the Poor-law Medical Officers' Association, will speak, supported by other speakers conversant with the working of these institutions.

MR. REGINALD B. D. ACLAND'S annual address to the members of the Hospital Saturday Fund is issued in pamphlet form and published at the offices of the Fund, 59, Farringdon-road, E.C., at the modest price of 1*d*. It is worth a perusal by all who take an interest in the work of our hospitals.

LORD RUSSELL OF KILLOWEN presided on Tuesday night last at the Freemason's Tavern over the annual dinner in connexion with King's College Hospital. During the evening subscriptions and donations amounting to £3340 were announced towards the debt of £6000 under which the hospital lies.

COUNT DEYM, the Austro-Hungarian Ambassador, has promised to preside at the fifty-first anniversary dinner of the German Hospital, which will take place at the Whitehall Rooms on June 26th next.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held at the Town Hall, Wandsworth, on the 8th inst. A paper was read by Dr. P. Cauldwell Smith, medical officer of health of Wandsworth, on the Vaccination Laws and their Amendment. A discussion, followed in which Dr. Morgan Dockrell, Mr. T. A. I. Howell, Dr. Gilbert Richardson, and Mr. W. G. Dickinson took part.

ÆSCULAPIUS LODGE.—The last meeting of this lodge for the Masonic year was held at the Café Royal, Regent-street, W., on Wednesday, the 8th inst. G. Crawford Thomson, M.D. Durh., the Master, presided. Thomas Dutton, M.D. Durh., M.R.C.P. Edin., was elected Master for the ensuing year; G. Danford Thomas, M.D. Brux., treasurer; and C. M. Simpson, M.R.C.S. Eng., and George Herschell, M.D. Lond., auditors. G. Rowell, F.R.C.S. Eng., was elected a joining member, and J. Campbell Maclean, M.B., C.M. Edin., and Thelwell Pike, M.D. St. And., were proposed as such. W. Stacey Colman, M.D., M.R.C.P. Lond., and C. Henson Broadhurst, L.R.C.P. Lond., were admitted to the second degree. The sum of 10 guineas was voted to charity. Other business being disposed of the lodge was closed. The members afterwards dined together, when the usual Royal and Masonic toasts were duly honoured.

THOMAS WAKLEY,

THE FOUNDER OF "THE LANCET."

A BIOGRAPHY.[1]

CHAPTER XVI.

Bransby Cooper v. *Wakley.—Sir James Scarlett's Address.—The Witnesses for the Plaintiff.—Wakley's Reply.—The Verdict.—The Results of the Trial.—The Solid Opposition to Wakley and his Solid Following.—The Attitude of the Public and the Profession.—Wakley's Expenses in the Trial Defrayed by Public Subscription.*

ON the morning of Saturday, Dec. 13th, 1828, before an immense and very excited audience, Sir James Scarlett rose to address the jury in behalf of the plaintiff, Mr. Bransby Cooper. His opening words betrayed his irritation at the position in which Lord Tenterden's decision of the previous day had placed him. He complained acrimoniously that his client, a gentleman seeking redress for one of the most injurious attacks upon fame and fortune that had ever been brought to the cognisance of a court of justice had been placed during an entire day upon his defence as though he were the defendant and the indictment a criminal charge. "I have no doubt," he said, turning to the jury, "that you are now sitting in judgment, not upon what reparation shall be made to an injured man for one of the basest calumnies any man could complain of, but whether Mr. Cooper is not a party unworthy of his situation, who has contributed to shorten a man's life." He then briefly sketched Mr. Bransby Cooper's honourable and successful career. This started with pupilage at the Norwich Hospital—a not irrelevant fact, for the ancient city was famous in those days for its skilled lithotomists, vesical calculus being a common malady with the dwellers on the chalky soil of Norfolk. From Norfolk he came to Guy's Hospital, and on completion of his time there accepted a commission in the Royal Artillery and saw service on the Continent and in Canada for three years with credit to himself. In 1816, at the termination of the dispute with America, he left the army and after a short sojourn in Edinburgh returned to Guy's Hospital as apprentice to his uncle, Sir Astley Cooper. His apprenticeship expired in 1823, when he was made demonstrator of anatomy. In 1825 he was elected assistant surgeon to the hospital. From that time forward until the publication of the libel not a word had been said against him, and counsel ridiculed the idea that Sir Astley Cooper would ever have employed a man as his assistant or his deputy in the most important surgical practice in the world without being fully assured, nephew or no nephew, that he was a highly competent operator. He attributed Wakley's accusations of nepotism to an unbalanced sense of the importance of THE LANCET, which had arrogated to itself a position of censor of professional manners and morals. Sir James Scarlett then explained the operation of lithotomy, very lucidly considering that he was only able to employ lay terms, and dwelt on the difficulties that might arise in its course. Coming to the particular operation the performance of which formed the subject of the libel, he traversed most of the statements and all the insinuations contained in THE LANCET report. So far from the patient being a healthy countryman he was, said Sir James Scarlett, a stout man with a hectic complexion and disordered kidneys upon whom the operation was not performed until the agony that he suffered precluded any other course. The delay and the employment of the various instruments were due not to any error on Mr. Bransby Cooper's part but to the peculiar difficulties of the case and the awkward position of the calculus. The appearances in the cadaver were, he maintained, all of them in agreement with this view, save one rent in certain soft, easily lacerated tissues. This rent, it had been insinuated by THE LANCET reporter, had been made by Mr. Bransby Cooper's ill-directed attempts to reach the bladder with various instruments. It was, as a matter of fact to be proved by the oaths of persons who had examined the parts before the agent of THE LANCET had handled them, made by that agent himself after death. He denounced Mr. Lambert as a hireling, instigated by malice to write untruths, ignorant, and absolutely wanting in all decent feeling, as shown by the dramatic form into which he had cast his false report, and he wound up a vigorous piece of advocacy by asking the jury to mark their sense of indignation at the treatment that the plaintiff had received by awarding him exemplary damages. He then called Mr. Callaway, who had assisted Mr. Bransby Cooper in the performance of the operation.

Mr. Callaway testified to two things of importance—the first was that Mr. Bransby Cooper's original incision was rightly directed; the second was that the situation and shape of the stone were such as to make the extraction necessarily tedious and difficult. He confirmed THE LANCET report in many details, such as that numerous different instruments were used, that a second incision into the bladder had to be made, and that the operator during the operation did say that he could not explain the cause of the delay; and he admitted in cross-examination that in his opinion Mr. Bransby Cooper had no knowledge of the situation of the stone. Mr. Callaway was the only medical witness called by Sir James Scarlett who actually saw the operation upon which the alleged libel was founded. The other medical witnesses were called to testify to the general difficulty of the operation and to the high character of Mr. Bransby Cooper, whilst they added for the benefit of the court their expert opinion of what had happened founded upon Mr. Callaway's evidence.

Mr. C. Aston Key, senior surgeon to Guy's Hospital and Mr. Bransby Cooper's brother-in-law, came first; then Mr. Laundy, a general practitioner, who stated that he was present once at the same operation when it was performed by that celebrated surgeon and anatomist the elder Cline, on which occasion the proceedings lasted an hour and forty minutes. Mr. Brodie, afterwards Sir Benjamin Brodie, of St. George's Hospital, President of the Royal College of Surgeons of England and of the Royal Society; Mr. Benjamin Travers, surgeon to St. Thomas's Hospital, Mr. Joseph Henry Green, surgeon to the same institution, and Mr. Dalrymple, surgeon to the Norwich Hospital, considered that Mr. Callaway's evidence showed that the skill of the operator could not be impeached.

Dr. Hodgkin, lecturer on morbid anatomy at Guy's Hospital, gave important evidence. He thought that in the unfortunate patient there had been present an anatomical conformation of the parts as revealed by post-mortem examination that would have rendered the operation a difficult one. He swore that Mr. Lambert came to him and asked permission to see the parts, and was allowed to do so in his (Dr. Hodgkin's) absence. That on his return Mr. Lambert showed him a certain rent, the rent which it was insinuated in the report had been caused by Mr. Bransby Cooper's bungling. He at once taxed Mr. Lambert with having made the rent, it being his firm conviction that it had been made after death.

Last came Sir Astley Cooper. He confirmed the statements as to his nephew's honourable and successful career, and said that no one save the man actually operating could judge fairly of the difficulties of an operation. He gave as an

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., and XV. were published in THE LANCET, Jan. 4th, 11th, 18th, and 25th, Feb. 1st, 8th, 15th, 22nd, and 29th, March 7th, 14th, 21st, and 28th, April 4th and 11th respectively.

Digitized by Google

explanation of the cause of the delay in the operation the fact that the bladder was empty and narrated a case in point where contraction of an empty bladder over a calculus had caused a skilful surgeon "now present in the court" to take an hour to effect the extraction.

This completed the plaintiff's case and Wakley rose immediately to reply. He said it was most remarkable that out of 200 persons present at the operation the plaintiff had thought proper to call only one—a solitary one—to give evidence to his skill on the occasion out of which the libel arose, whilst a host of persons who knew nothing at all of that operation were called to speak to his professional ability. This he characterised as an attempt to practise an imposition on the jury and on the public, but he hoped that the jury would not be persuaded by the general opinion of men not present at the operation that the specific facts spoken to by THE LANCET report did not occur. He pointed out that Sir James Scarlett had devoted a considerable part of his speech to miscalling Mr. Lambert THE LANCET reporter. Of course Mr. Lambert was a hireling, said Wakley. He was paid for his contributions to THE LANCET just as Sir James Scarlett was paid for the advocacy of Mr. Bransby Cooper. Wakley then cautioned the jury against the evidence of "a gang of hospital surgeons" only one of whom had seen with his own eyes the things to testify to the accuracy of which or otherwise they had been called. They stuck to Mr. Bransby Cooper because they knew that his case might some day be theirs. They had come there to bear down the weight of honest testimony by their names and influence. The question, he contended, was not the abstract one whether lithotomy was or was not a difficult operation, but the particular one, whether Mr. Bransby Cooper had performed a certain operation with due skill. He begged the jury to ask themselves whether they would be willing to employ the plaintiff as a surgeon if it were necessary for them to undergo this operation. And if they would not, he maintained that they must give a verdict which would prevent the plaintiff from returning to Guy's Hospital. He wound up an eloquent rather than a closely-reasoned speech by an impassioned appeal to the jury to consider the case of the poor in giving their verdict—the poor who were at the mercy of the hospital surgeon. For himself, he said, he cared nothing. He was willing to go to prison, and willing to give up THE LANCET if that were found to be the course that justice dictated, but unless the jury considered that Mr. Bransby Cooper had performed this operation properly the plaintiff must be denied a verdict.

At the conclusion of his speech, which elicited loud applause in court, Wakley was so overcome with excitement, fatigue, and heat that he had to be supported into an adjoining room.

Lord Tenterden then proceeded to sum up the case. He recapitulated the evidence for the jury and spoke severely of the manner in which the report had been drawn up for THE LANCET. If the jury thought that the defendant had proved the unskilfulness of the plaintiff they were bound to give him their verdict, but they must remember that unimpeachable evidence had been given by Mr. Bransby Cooper's witnesses to the facts that numerous instruments were sometimes required in the performance of a lithotomy, and that the operation had failed many times when undertaken by most skilful surgeons. He did not agree with the plaintiff's counsel that the damages awarded, if any, should register feelings of indignation; on the contrary, a verdict should mark cool and deliberate consideration of facts.

The jury were absent for two hours, and on their return to court delivered a verdict for the plaintiff, damages £100.

The results of the trial were not at first apparent. The verdict constituted a victory for both sides or neither. Wakley had to pay £100 in damages and nearly three times that amount in costs for having published a malicious libel. But Mr. Bransby Cooper's was a much worse plight. The sum awarded to him bore no sort of proportion, however distant, to the evil that had been said of him. Damages £100 for such an accusation! The verdict told its own tale. Most certainly the jury believed Wakley's main statement—that the plaintiff had been guilty of malpraxis. On no other ground whatever could they have let him off so cheaply, having regard to the things that he had printed. He had accused Mr. Bransby Cooper by inference of manslaughter, making no secret of his belief that the death of the patient was the direct outcome of the ignorance of the surgeon. Mr. Bransby Cooper was a man of thirty-five years of age, enjoying a good private practice and a honourable public position. The things that had been said of him were calculated to utterly ruin him. If proved true, his not inconsiderable scientific prestige together with his large and increasing income were both lost to him. Grave as the consequences would have been to Mr. Bransby Cooper if Wakley had obtained a verdict, heavy in due proportion should have been the damages when a verdict was given the other way. Yet of the £2000 demanded—a by no means exorbitant demand when the nature of the libel is considered—only £100 were awarded. The jury paltered. They wished to do their duty. They felt that Mr. Bransby Cooper did not shine as an operator and that the defendant had made out his justification; but they did not consider the libel a decent account of what had happened. So they marked a general disapproval of both sides by awarding to the plaintiff a barren victory.

The enormous interest taken in this case by the public as well as the profession made of it a landmark between the times when all sorts of abuses were rife and the times when the profession as a whole set itself, under Wakley's energetic direction, to work out its own salvation. As has already been said, when Wakley announced his intention of supplementing his reports of the lectures of hospital surgeons by accounts of the operative proceedings at different institutions he crossed the rubicon and declared war on the heads of the profession. They looked upon his action as one of intolerable aggression to be resisted in all conceivable ways. Skirmishes had since occurred in which the victory had lain now with one side and now with the other. Here and there Wakley's reporters had been turned out of the hospitals, while on several occasions Wakley had been able to print details of hospital management or treatment the reverse of creditable to those responsible for them, and to distribute nicknames, ridiculous yet adherent. But these were but skirmishes, while the case of Bransby Cooper *v.* Wakley was a pitched battle. Everything that it was possible to say fairly against Wakley's methods in issuing THE LANCET could be said in reference to this case. The evidences of personal ill-feeling against a certain group of distinguished men was not wanting in it, and its publication was bound to hold the profession up to the contempt of laymen. A solid feeling of anger among the hospital officials, medical and lay, was created by Wakley's line of defence, and the damages exacted from him were not sufficiently high to cause any compensating satisfaction. At no time in his career had the Editor of THE LANCET such bitter and organised opposition to meet as immediately after this sensational trial. His reporters were expelled from the learned societies, he himself was excluded from the walls of three or four of the largest metropolitan hospitals, and, lastly, the other medical papers of the day, such as they were, were supported by all Wakley's foes, the facilities denied to THE LANCET being given to its rivals. The partiality of this proceeding touched Wakley nearly; the rest concerned him not a whit, for the

Digitized by Google

offers to assist him with information were numerous almost to the point of constituting a nuisance. But the difference made between THE LANCET, the pioneer of reform, and its imitators galled him. He had the pride of a parent in his paper, and he did not like to see the bantlings of others favoured at the expense of his sturdy offspring, however natural the preference might be in those who showed it. Wakley had been called, and was still called, a thief for reporting hospital lectures, and a malicious slanderer or a panderer to morbid tastes for publishing hospital reports. In spite of all that had been said he had persevered in his ill-doing, believing it to be exceeding well-doing. But when the leaders of the profession saw that a measure of publicity was to be their fate, while not abating their animosity to THE LANCET they permitted the editors of other journals to do what they found in Wakley to be hideous crimes. This injustice he felt, and the feeling found vent in savage criticism of his contemporaries. They in their turn wrote in unspeakable terms of him, and the recriminatory passages, certain of which will have to be quoted in connexion with Wakley's actions against Dr. Macleod, the editor of the *Medical and Physical Journal*, and Dr. James Johnson, the editor of the *Medico-Chirurgical Review*, form amazing reading for these politer days.

But if Wakley had by this time created a solid opposition he had behind him a solid following. The case, which had given common cause for terror and affront to hospital officials, had justified the policy of THE LANCET and came as a verification of the most burning of its Editor's words to the profession at large and also to the public. Never had Wakley said anything in his declamations against the evils of nepotism and the ineptitude of hospital officials that approached in severity the words that *should* have been used concerning the operative procedures at St. Thomas's Hospital supposing Mr. Bransby Cooper had bungled as Wakley alleged. And that he had so bungled Wakley continued to declare, asserting that THE LANCET had been cast in damages simply because of the bad impression created by the form of Mr. Lambert's report. The profession at large and the public believed Wakley, and the solid opposition of the authorities converted him in their eyes into an ill-used man. A numerously attended public meeting was held at the Freemason's Tavern on the Tuesday following the verdict, at which the following resolutions were proposed:—

1. That the best interests of the medical profession and of the public are identified with the cause of medical reform, and that Mr. Wakley, as Editor of THE LANCET, having given the first impulse to that cause, and having subsequently advocated it with undeviating firmness and fidelity, is entitled to the cordial thanks and support of this meeting.

2. That the purposes for which the hospitals and infirmaries of the metropolis were founded, and that the views of the humane contributors to their funds are materially promoted by the weekly publication of reports detailing the medical and surgical treatment of the unfortunate patients, and that Mr. Wakley, having originated the practice of publishing hospital reports, has conferred important benefits on medical science and on the cause of humanity.

3. That the independent and imperial principles on which THE LANCET were first established have been preserved by Mr. Wakley at all risks; and that a subscription be opened for the purpose of defraying the expenses of the late action.

4. That in accordance with the feelings that this meeting has expressed Mr. Wakley be invited to attend a public dinner, and that a committee be nominated to arrange the same.

The first and third of these resolutions were carried by a very large majority—five dissentients only among 300 persons; the second and fourth were agreed to unanimously. In accordance with the third resolution a public subscription was opened, Wakley asking for £407 7*s*. 9*d*., being £295 10*s*., Mr. Bransby Cooper's costs, £100 his damages, and £12 17*s*. 9*d*., the Sheriff's poundage.[1] The sum was immediately subscribed, and the books were closed when the required total was reached, while two or three belated subscriptions which the donors did not wish to have returned to them were forwarded to the widow of Mr. Bransby Cooper's late patient.

There is one very pleasant thing to relate as an appendix to this sad and even terrible passage in Wakley's life. In after years he met Mr. Bransby Cooper and a formal reconciliation took place between them.

(To be continued.)

MIDWIVES BILLS.

IT is said that the second reading of the Midwives Bill is fixed for May 6th. It needs little political knowledge to say that in the present aspect of politics the chance of legislation on this subject is the very smallest, unless some disposition to agree with each other be shown among the advocates of such legislation. For we have no longer to deal with one Bill, but with several; they are becoming numerous and difficult to count. There is the Bill already before Parliament, ostensibly the old Bill, with the provisions of which we are all pretty familiar, but with alterations that do not seem to us improvements. There are the various changes recommended by the General Medical Council when this Bill was referred to it last year by the Government. Next comes the Bill of the Parliamentary Committee of the British Medical Association. Then the Lancashire and Cheshire Branch of the British Medical Association have properly applied their critical faculty to the Bill of the Parliamentary Committee and produced a complete Bill of their own. Possibly the Parliamentary Committee and the Lancashire and Cheshire Branch may come to terms with each other and produce a single Bill that will satisfy both the Committee and the Branch. Then there is the outline of "A Bill for the Prevention of Puerperal Fever" by Dr. W. Fraser, which will be found in THE LANCET of Feb. 29th. There is yet another document emanating from 143 gentlemen, including Dr. Rentoul, who are opposed to the registration of midwives in the way hitherto proposed in Parliament, but who realise the gravity of puerperal mortality and who "are anxious to improve the education of midwifery nurses and, if need be, to support a practical scheme of local registration. They do not object to the registration of midwives provided they act as midwifery nurses *only*, under the immediate supervision of medical practitioners, and are registered as midwifery nurses *only*. Nor do they object to such proposed legislation as would protect any of the present privileges of existing midwives." Here there are no less than six more or less distinct proposals for the purpose recognised by all parties of protecting lying-in women of the poorer classes from the mischief and the mortality that attach to the practice of ignorant and untrained midwives.

The Bill now before Parliament is ostensibly what has been hitherto known as the Midwives Bill, with clauses for the registration of existing midwives and of women who have had a certain amount of training and passed an examination under rules framed by a Midwives Board created by the Bill and approved by the General Medical Council. We say this is ostensibly the old Bill. But it differs and does not differ for the better. We miss in it the explicit limitation of the midwife to natural labour. And it is noticeable that nearly all the suggestions of the General Medical Council for its amendment are not adopted. This is a very remarkable circumstance, which throws a great responsibility on its promoters. The General Medical Council suggested the substitution of the title of midwifery nurse for that of midwife. This is not adopted.

[1] It will be seen that the correct addition of these sums amounts to £408 7*s*. 9*d*., but by an oversight one pound too little was asked for.

Digitized by Google

The definition of the term midwife as one who undertakes to attend "cases of natural labour" is not adopted, and the clause dealing with the privileges of midwives is greatly altered from the similar clause in the previous Bills of the sort and is remarkable for not specifying, as the former Bill did, that in the certificate to be given under the Act the woman shall be restricted to cases of natural labour only. It is quite true that under Clause 12, Sub-clause 5, the omission to send for a medical practitioner where the case is not one of natural labour is regarded as a form of misconduct for which the midwife may be removed by the Midwifery Board from the Midwives Register. But the limitation should be clearly defined in a separate and early clause, as in the first Bills of the sort. We cannot notice all the points in which the promoters of the Bill have failed to accept the suggestions of the General Medical Council, but we must specify another. The General Medical Council expressed a decided opinion that existing midwives, as one of the conditions of registration, should produce some evidence of character and capacity. This condition does not appear in the wide clause for registering existing midwives in the present Bill. Surely, too, it is somewhat absurd to give a midwife who is dissatisfied with the penal action of the Midwifery Board the right of appeal to the Privy Council—a right which medical men do not possess under the Medical Acts.

The Bill of the Parliamentary Committee and that of the Lancashire and Cheshire Branch may be considered together. But they differ materially. The former follows the line of the old Midwives Bills, only substituting the title midwifery nurse for that of midwife, and clearly limiting the function of such persons to cases of natural labour. It penalises the use of the titles "midwifery nurse or midwife," or any word implying registration under the Act by those not registered. In addition—and this is the chief difference—the Bill of the Lancashire and Cheshire Branch, in a new section, penalises to the extent of £5 unregistered persons who, after a certain interval, "habitually for gain" attend women in labour, always and properly excepting those attending a woman during labour in a case of emergency. It is difficult to see how "women and newly-born infants are to be protected from the practice of midwifery—nursing by ignorant and untrained persons"—the purpose set forth in the preamble of the Bill of the Lancashire and Cheshire Branch—if some such prohibition is not made clear. But it must be made equally clear that no terror is contained in the Act for kind people acting in emergencies and in remote places. One of the most important features of the Bill of the Lancashire and Cheshire Branch is its large definition of the word midwifery nurse: it is said to mean, "A woman who attends cases of natural labour, *and afterwards tends the mother and child during the lying-in period under such rules, regulations, and medical control or supervision as may be from time to time laid down by the Midwifery Nurses' Board.*" Both Bills create a Midwifery Nurses' Board, to be appointed by the General Medical Council. In the Midwives Bill such a board is to consist of 12 registered practitioners, 3 appointed by the Royal College of Physicians, by the Royal College of Surgeons, and by the Apothecaries respectively, 3 by the Incorporated Midwives Institute, and 3 by the Lord President of the Council, 1 of whom, at least, shall be a woman. The Parliamentary Bills Committee requires the General Medical Council to appoint a Midwifery Nurses' Board of 12. The Lancashire and Cheshire Branch provides that the General Medical Council shall appoint the board to consist of 29 registered medical practitioners to be distributed as follows: for London and southern counties, 7 representatives; Birmingham, midland, and eastern counties, 5; Lancashire, Cheshire, Westmorland, and Cumberland, 6; Northumberland, Durham, and Yorkshire, 6; Wales and counties of the west of England, 5. The duties of the board are to frame rules of course of study, prescribe the subjects to be studied and the general standard, to frame rules for regulating the practice of midwifery nurses, all subject to the approval of the General Medical Council. The Bill of the Lancashire and Cheshire Branch in several additional sub-clauses defines the powers of the board. The Bill of the Parliamentary Committee strangely makes erasure from the register of a midwifery nurse "for infamous conduct" the act of the General Medical Council. That of the branch empowers the Midwifery Nurses' Board to appoint a committee or committees of not less than 3 to investigate charges, and gives to such committee or committees the power of erasure. The Bills are not explicit as to places of meeting, examination, &c. Both Bills, for reasons which it is difficult to understand, make the General Medical Council responsible for the register of midwifery nurses and for its publication In the Bill before Parliament it is one of the duties of the Midwifery Nurses' Board to establish and keep the register. It is obviously important that each locality should have an easy way of knowing whether its midwives or midwifery nurses are registered. The Bill now before the House provides that one copy free of charge be sent to each county council. In the Bill of the Parliamentary Committee it is provided that each medical officer of health be supplied with a copy. The Bill of the Lancashire and Cheshire Branch requires such a copy to be sent to the clerk of the local sanitary authority. Dr. Rentoul and those who agree with him would support a local registration of midwifery nurses We can only notice one point more in these Bills—that of fees. It is obvious that this system, however humble or local, cannot be worked without fees. The Bill before the House fixes the fee to be paid by women for examination at 2 guineas. The Bill of the Parliamentary Bills Committee and that of the Lancashire and Cheshire Branch leave the sum to be fixed by the Midwifery Nurses' Board. They provide that all moneys should be paid to the General Medical Council and all expenses be paid by that body. The branch thoughtfully adds that in case of any deficit arising it shall be paid out of Her Majesty's Treasury.

It remains only to notice shortly a contribution to the discussion of this subject in THE LANCET of Feb. 29th, 1896, by Dr. W. Fraser, entitled, "Suggested Outline of an Act for the Prevention of Puerperal Fever." Therein it is proposed that the medical officer of health shall keep a register of midwives. After twelve months no midwife is to be placed on the register without a certificate satisfactory to the General Medical Council, and no medical practitioner is to take a pupil or give a certificate unless sanctioned by the General Medical Council. The Local Government Board is to issue directions to midwives. The medical officer of health may prevent any woman attending cases for a period not exceeding six months. Appeal lies to the medical officer of the county. The medical officer of health is to make full inquiry into all puerperal deaths from sepsis in his district. The medical officer of health may prohibit any midwife or other person engaged in nursing from practising for two months under a penalty of not more than £20. Every medical officer of health may inspect the residences of midwives. A record of those midwives habitually receiving pregnant women into their houses is to be kept The record and the house shall be open to the inspection of the medical officer of health. Every registered practitioner may report a midwife to the medical officer of health or to her examining board for any breach of instructions supplied by the Local Government Board. Every registered midwife shall have power of recovery of charges for attendance as a midwife nurse. Every medical officer of health may warn unregistered persons assuming titles or practising midwifery. Should the offender disregard the warning she will be liable to a penalty of not more than £20. Medical practitioners are to notify still-births to the medical officer of health and to receive a fee of 2*s.* 6*d.* Any person interring, or certifying for the interment of, still-births without the authority of the medical officer of health is to be liable to a fine of £10. Sanitary authorities are to pay medical officers of health for their trouble under this Bill.

DR. DE BOSSY OF HAVRE, stated to be the oldest medical man in France, celebrated his 104th birthday on Good Friday.

ROYAL METEOROLOGICAL SOCIETY.—The monthly meeting of this society was held on Wednesday evening, the 15th inst., at the Institution of Civil Engineers, Westminster, Mr. E. Mawley, President, in the chair. Mr. E. D. Fridlander, B.Sc., gave an account of some observations of the amount of dust in the atmosphere made at various places during a voyage round the world in 1894–95. Not only did dust occur in the air of inhabited countries, over the water surfaces immediately adjoining them, and up to an altitude of 6000 or 7000 ft. among the Alps, but it was also found in the open ocean, and that so far away from any land as to preclude the possibility of artificial pollution, and its existence has been directly demonstrated at a height of more than 13,000 ft.

THE HISTORY, METHODS, EXPENDITURE, AND POLICY OF THE CIVIL RIGHTS DEFENCE COMMITTEE.

(*Continued from page 576.*)

IN THE LANCET of Feb. 29th we gave a summary of the objects and aims of the Civil Rights Defence Committee, and we now proceed to afford some further particulars concerning its origin and operations.

When Mr. R. B. Anderson was illegally imprisoned in Trinidad Mr. Conrad F. Stottmeyer, one of the oldest and most respected inhabitants and subsequently Mr. Anderson's surety, Mr. Toppin, and Mr. Wayman consented to act as trustees to a fund to be called the Civil Rights Defence Fund, to enable Mr. Anderson to proceed to England to lay the grievances of the colony before the public and to seek redress for his own wrongs. In all about £150 were subscribed, and out of this advances of 7*s.* a day were made to Mr. Anderson during the greater part of three and a half months he was kept under an excessive and illegal bail of £1000 to enable him to live to come to England. When this allowance was discontinued Mr. Anderson visited Barbadoes, a colony enjoying the advantage of representative institutions, which the colonists, being a spirited and independently minded people, have most jealously guarded ever since the colonisation during the Civil War in the seventeenth century. There he stayed for about six weeks, and was instrumental in founding at a public meeting the West Indian Civil Rights Defence Association, since called the West Indian Union, with branches in other West Indian colonies, and its monthly journal, the *Civil Rights Guardian*.

Coming to England well provided with introductions, credentials, and sworn evidence, Mr. Anderson obtained a hearing in many quarters, and his friends being impressed with the gravity of the grievances and oppression of a British colony including his own, constituted themselves into a society under the name of the British and West Indian Alliance, to take up and investigate, on the part of the people of this country, the complaints of the West Indies, and to coöperate with, and act in England for, the West Indian Union in all cases approved by the Alliance. On Sept. 4th, 1891, Mr. Anderson delivered at St. James's Hall, before the Balloon Society of Great Britain, a lecture entitled "A Plea for the West Indies," and this secured useful support. He obtained interviews with the British Foreign Anti-Slavery Society and the Aborigines' Protection Society, and won their acquiescence at least. Mr. Anderson also obtained an interview of three-quarters of an hour with one of the permanent secretaries and one of an hour with Lord Knutsford, the Secretary of State for the Colonies, but these interviews resulted only in the usual official *non possumus*. Subsequently the Alliance held a meeting at St. James's Hall and another at Southport. Meanwhile, Mr. Anderson had commenced his action against the three Trinidad judges, and had obtained from Sir Francis Jeune special leave to serve the writ on Sir John Gorrie in Trinidad out of the jurisdiction, and he succeeded also in serving Mr. Cook and Mr. Lumb in England, just catching the latter on board ship at Southampton as he was leaving for Trinidad. On this a motion was made in the Legislative Council in Trinidad for an inquiry into the judicial administration, and was carried by a majority of six to two of the unofficial members, the officials being permitted to abstain from voting. The application for inquiry was backed up by strong representations to Lord Knutsford and to the Prime Minister, Lord Salisbury, on the part of the Council of the West Indian Alliance. Lord Knutsford made some concessions and Sir W. Markby and Sir F. Pollock were sent out as a Royal Commission to investigate the complaints which had been made. A Committee of the Legislative Council of Trinidad and Tobago was applied to to conduct the prosecution of the charges. This prosecuting Committee in Trinidad telegraphed to Mr. Anderson to come out and to give evidence in Trinidad and to conduct the prosecution for them in Tobago and remitted the money to enable him to do so. It so happened that in the action against the Trinidad judges which Mr. Anderson instituted in September, 1891, in the Court of Queen's Bench, and which he had been conducting quite independently of the Alliance and the funds provided by Trinidad, a stay of proceedings had been obtained by the defendants in order that they might be placed in possession of the particulars of the damages sustained by Mr. Anderson for which they had asked. This lull enabled Mr. Anderson to proceed to Trinidad and give his evidence, but the Commissioners did not go to Tobago. The result of the inquiry was the amotion of Mr. Cook from office and the interdiction of Sir John Gorrie pending charges being brought against him. Prior to returning home Mr. Anderson visited several of the West India islands, holding meetings to strengthen the branches of the Union and establish others. After his return he laid his case before the British and West India Alliance, and its Council warmly espoused it. A deputation, consisting of General Graham, Mr. T. Shepherd Little, M.P., the Hon. Stuart Erskine, and other gentlemen, waited on the Council of the British Medical Association, which had previously gone fully into the details of the case, and now, Jan. 11th, 1893, in response to the deputation, adopted a resolution authorising the editor of their journal to publish Mr. Anderson's case for his benefit amongst the members of the Association, and the Parliamentary Bills Committee to do what they could to further the steps which he was taking in his application to the Privy Council. In this way a subscription was promoted and about £42 were raised, enabling the initial steps of the appeals to the Privy Council to be taken. That the response in a case involving professional rights so important and individual wrongs so unprecedented was not more general was probably due to the fact that the importance of defending these rights and redressing these wrongs did not come home to the profession in England until later, when the judgment of the Court of Appeal made Mr. Anderson's wrongs without remedy, and showed that medical men are absolutely at the mercy of all judges of record both for the recovery of their charges and their own personal safety. Besides this, amongst a certain section of the profession there is a mistaken repugnance to claiming the right to be paid for their services, although Mr. Anderson had claimed it in a way the least harsh and exacting that could be devised and under circumstances which compelled him to do it or be cheated with his eyes open—an example which would have been contagious in a colony like Tobago. Moreover, the course which Mr. Anderson had taken to compel the Colonial Office to investigate the Trinidad scandal was very much resented by the Department, and without being able to trace the source of the scandals Mr. Anderson found that a report was being widely circulated both within and outside the profession that he was a mischievous, cantankerous, meddlesome agitator. Added to this the wrongs which he had endured were so outrageous as to seem almost incredible to all who had not some insight into the matter, to prevent people from investigating the case and to lead them to conclude that some defect in Mr. Anderson's conduct had been a prime factor in the case, instead of his indomitable courage enabling him to survive an ordeal to which others had been induced to succumb. Thus the very iniquity of the wrongs done to him seemed likely to deprive him of all hope of redress.

The first and strongest accession of help brought by the investigation carried out by the Commissioners was that of Bishop Mitchison, formerly Bishop of Antigua, in the Leeward Islands, who wrote that "after reading the damning report of the Royal Commission he could no longer abstain from taking part with the Alliance in the movement." About this time Mr. Anderson was in his worst and greatest difficulty. His own relatives did all in their power to help him; an aunt, now in declining years, sacrificed nearly her all, and other friends who could ill spare it have assisted him to the best of their ability. His pension of £50 goes to support his wife and family in Tobago, and all that he has has been devoted to his immediate necessities. At this juncture Mr. Anderson obtained help from certain friends, without which it is difficult to see how he could have lived to carry on the struggle. The same may be said of the help which he has had from time to time from many sources, for seldom from month to month, from week to week, and sometimes from day to day, has Mr. Anderson known whence would come either the means of subsistence or the means to carry on the contest against the whole strength and influence of the official and judicial powers of the State, which seemed to be perverted to oppress him, wear him out, and crush his resistance. In Trinidad during the long delays in hearing his appeals, deliberately devised for the end just specified, Mr. Anderson for ten

Digitized by Google

months out of eighteen was the guest of Mr. Tucker, who till he went there to oppose the decision of Sir John Gorrie had scarcely known him by sight. It will here be as well to point out that Mr. Anderson took extreme precautions to secure evidence and support in regard to the general oppression of himself and his fellow colonists. He obtained statutory declarations from clergymen and magistrates which he read with telling effect both in Barbadoes and at St. James's Hall. He had the concurrence of many fellow petitioners in the petitions sent to the Queen in Council. As to his professional conduct he had the written testimony of the only three other medical men in the island of Tobago. He also obtained unanimous votes in support of his professional conduct and rights from the Barbadoes Branch of the British Medical Association, and subsequently, on its formation, from the Trinidad and Tobago branch, so both as to his statements of the injuries done to himself and his fellow colonists and as to his own conduct he occupies a practically impregnable position, and of this these facts, coupled with the report of Sir W. Markby and Sir F. Pollock, should convince the most sceptical.

(To be continued.)

THE NILE EXPEDITION.

THE latest intelligence from this expedition shows that there is great activity at Wady Halfa and that preparation is general for the advance of the force. There are two points on which the authorities may, we think, be fairly congratulated. The first is that the feeling with which the expedition is regarded by some of the tribes in the Soudan appears to have undergone a great change in our favour. Some of those who fought against us at El Teb and Tamai have now become friendly and have not only proffered help to the expedition, but have been making a series of attacks upon Osman Digna's forces, and others have been doing useful work as scouts outside the limit of our own military operations. The other encouraging factor is that the report of the Anglo-Egyptian movement on the Nile has had the effect of drawing off a portion of Osman Digna's troops from Kassala in other directions, thereby enabling the Italian garrison of Kassala to make a successful sortie and defeat the force besieging that place. Official telegrams from Massowah state that the Dervishes threatening Kassala have been routed and driven across the River Atbara, and that the stores of the garrison have been recently replenished. The latest news, moreover, is to the effect that Italian troops will continue to hold Kassala and that the Government do not intend to evacuate the position.

The work of the Transport Department of the Nile Expedition is being energetically pushed forward, and Wady Halfa has been for some time, and still remains, as we have said, a scene of great activity. The railway has now been completed some miles beyond Sarras, and will soon be extended to Akasheh. Rations for the whole force for the next four or five months are being landed and stored at Wady Halfa, and, in short, all arrangements are being made for a serious campaign in the autumn, up to which time the troops will most probably not advance beyond Akasheh, between which place and Wady Halfa railway and telegraphic communication will have, in the meantime, been established.

In addition to the gathering of the Dervishes in and about Dongola a considerable portion of Osman Digna's force seems to have gone in the direction of Suakim, the garrison of which place will no doubt require to be strengthened, but it is hoped and believed that the Egyptian force at Suakim and Tokar—with the aid of the neighbouring tribes friendly to us and strongly opposed to Osman Digna's rule—will be quite sufficient for the present to cope successfully with any troops which Osman Digna can bring against them.

The medical arrangements on the Nile will be a hospital for the Egyptian troops of 340 beds at Wady Halfa, which will act as the provisional base of the expedition, in addition to a portion of the barracks converted into a hospital, a section of a field hospital at Sarras, a hospital at Ambagol, and a field hospital of 100 beds at Akasheh. Hunter Bey, the senior medical officer of the Egyptian army, is making the arrangements, aided by Surgeon-Captain Trask and Surgeon-Captain Penton. It is hoped that river transport by native boats, which is far the most comfortable and best for sick and wounded, will be arranged for the conveyance of sick and disabled men from the stations in front to the base hospital at Wady Halfa. Until this is done their removal must be effected by *cacolets* on camels—an inferior, and indeed unsuitable, method for any sick or badly wounded men. Additional hospital provision and arrangements will have to be made for the British portion of the force. The heat is great—it reaches 107° F.—but it is commonly tempered by a cool breeze from the north at some period of the day. There are considerable diurnal variations of temperature—a difference of as much as 30° F. sometimes taking place between the temperatures of the day and night. The climatic heat is, however, very different to that of India. It is a matter of great importance, of course, that there should be no overcrowding of the troops, that any available means of free ventilation should be turned to account, that the soldiers—especially the European soldiers—should have good cover from the direct effects of the sun, that the camps and camping grounds should be kept scrupulously clean, and that there should be ample supplies of ice. The men of the British battalion are stated to be in fairly good health and in excellent fettle, but there has, as might have been anticipated, already been some inefficiency from sickness among them. As the result of all our previous knowledge and experience we may fairly expect that the principal diseases that will have to be encountered will be fevers—especially heat fevers and typhoid fever—diarrhœa and dysentery, with cases of sunstroke and heat-exhaustion. It is understood that British troops will not be sent to Egypt to take part in the campaign until the hot weather is over, and that Sir Redvers Buller will assume command of the expeditionary force when the advance on Dongola is made. As we have already said, the army generally has the greatest confidence in the proved capacity and soldier-like qualities of Sir Redvers Buller, who has already made a reputation for himself in the fields of South and North Africa. It seems to be generally agreed that great improvement has taken place in the military bearing, discipline, and general appearance of the Egyptian troops.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

SANITARY ADMINISTRATION IN THE PORT OF LONDON.

THE current half-yearly report of Dr. Wm. Collingridge, the medical officer of health of the Port of London, is very interesting reading, and it contains, moreover, suggestions of much value. The Cholera Surveys of recent years which have been undertaken by the Medical Department of the Local Government Board have done excellent work in serving to stimulate port sanitary authorities throughout the country to a better comprehension and execution of duties imposed upon them by the Legislature; and the energetic and praiseworthy action of the Corporation of London has provided a fitting example which other port sanitary authorities may well follow. It is surely in keeping with the spirit of the times that the port of the greatest city in the world should administer its affairs with no niggardly hand—it can, indeed, well afford to set an example both in administration as well as in liberality. During the half year referred to by Dr. Collingridge's report 14,054 sanitary inspections of vessels were made, and it was discovered that in 3·8 per cent. of these cleansing orders were necessary. In connexion with these inspections it is stated that the proportion of dirty forecastles has steadily decreased since systematic inspections have been carried out. Of the total number of vessels inspected, 82·4 per cent. were British, 9·05 were Swedish and Norwegian, 3·29 were German, and the remaining nations were represented in smaller percentages. Many of the improvements carried out during the year were in regard to lighting and heating, and Dr. Collingridge very properly insists strongly on the importance from a sanitary standpoint of affording as much light as possible. In connexion with the question of structural requirements Dr. Collingridge refers to the necessity of the port sanitary authorities inspecting the plans of all

Digitized by Google

vessels prior to their construction, as, although the officers of these authorities would have little to say to the design of a vessel, they would be able to suggest improvements as regards fittings, ventilation, lighting, &c., and thus spare infinite subsequent trouble to all concerned. The important modifications which have been recently introduced into the instructions of the Board of Trade as to the survey of crews' spaces, &c., are referred to with much satisfaction by Dr. Collingridge, and he especially mentions the prevention of condensation in the berths and the provision of proper lighting and ventilation. In the instructions referred to it is for the first time laid down that the minimum size of bunks in vessels built or measured after the issue of the instructions shall not be less than six feet long and two feet wide. Medical inspection on the part of London has, Dr. Collingridge observes, worked without a hitch and with but the least delay to shipping; he contemplates that the Quarantine Act when in force will by the removal of needless restrictions still further facilitate matters. The enormous amount of inspectorial work which is necessitated in the Port of London may be gathered from the fact that the limits of the district extend from Teddington to the Nore. It has been found, in fact, that with the two steam launches hitherto at the disposal of the sanitary authority it is impossible to carry out the inspection thoroughly over the whole area, and Dr. Collingridge has asked the authority to provide a third launch. He points out that under the Public Health (London) Act, 1891, it is as much the duty of the port sanitary authority to cause inspection to be made of the ships in their district as it is for an inland sanitary authority to inspect the houses in theirs, and he shows that with the present fleet such inspection is impossible. The port sanitary committee has had Dr. Collingridge's request under their consideration, and we are glad to see that before deciding upon the matter they adopted the very sensible course of themselves making trips down the river and thereby ascertaining the impossibility of complete inspectorial supervision with but two steam launches. A considerable portion of Dr. Collingridge's report is devoted to the important subject of food inspection, a matter which engages a large portion of the inspectors' time. For instance, during the six months under review there were destroyed 451 carcases of mutton and lamb and 1546 quarters of beef, besides numerous cases of eggs, fruit, and fish. A very large number of frozen rabbits and hares are imported during certain months of the year from New Zealand and Australia, and these are all inspected on their being unloaded from the vessels. Much care has to be exercised in dealing with these rabbits in transit from the docks, as they are extremely susceptible to changes of temperature and decomposition readily ensues. The importance of this supervision of our food-supplies entering by sea which is exercised by the officers of the London Port Sanitary Authority cannot be overrated, and Dr. Collingridge draws attention to the possibility of the introduction of infection by meat and milk, insisting that inasmuch as there is no information as to the condition during life of the animals which furnish the meat and milk it is necessary to be the more particular in subsequent examination. In the appendix to the report the sanitary committee have published the whole of Dr. Theodore Thomson's very thorough report to the Local Government Board upon his survey of the London Port Sanitary District. In conclusion, we commend Dr. Collingridge's report to port medical officers of health, and we trust it will find its way into their hands.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6451 births and 4164 deaths were registered during the week ending April 11th. The annual rate of mortality in these towns, which had declined in the five preceding weeks from 20·7 to 18·3 per 1000, rose again last week to 20·0. In London the rate was 20·3 per 1000, while it averaged 19·8 in the thirty-two provincial towns. The lowest rates in these towns were 13·0 in Brighton, 13·3 in Croydon and in Derby, 14·2 in West Ham, and 14·5 in Huddersfield; the highest rates were 22·0 in Salford, 24·7 in Oldham and in Bolton, 25·1 in Manchester, and 27·5 in Leeds. The 4164 deaths included 666 which were referred to the principal zymotic diseases, against 631 and 615 in the two preceding weeks; of these, 276 resulted from measles, 206 from whooping-cough, 76 from diphtheria, 42 from diarrhœa, 40 from scarlet fever, 24 from "fever" (principally enteric), and 2 from small-pox. No fatal case of any of these diseases occurred last week in Huddersfield; in the other towns they caused the lowest death-rates in Brighton, Cardiff, Bradford, Preston, and Hull, and the highest rates in Wolverhampton, Birkenhead, Bolton, Oldham, and Sunderland. The greatest mortality from measles occurred in London, Bristol, Oldham, Birkenhead, and Sunderland; from scarlet fever in Salford and in Bolton; from whooping-cough in Bolton, London, Salford, Leeds, and Derby; and from "fever" in Wolverhampton. The 76 deaths from diphtheria included 45 in London, 4 in Birmingham, 3 in West Ham, and 3 in Bolton. Two fatal cases of small-pox was registered in Bristol, but not one in London or in any other of the thirty-three large towns. There were 21 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 11th inst., against 43, 33, and 23 at the end of the three preceding weeks; 5 new cases were admitted during the week, against 9, 2, and 2 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2587, against 2773, 2744, and 2676 on the three preceding Saturdays; 226 new cases were admitted during the week, against 277, 224, and 186 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined in the six preceding weeks from 404 to 270, rose again to 301 last week, but were 102 below the corrected average. The causes of 73, or 1·8 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Salford, Oldham, Leeds, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Blackburn, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the three preceding weeks from 19·6 to 18·7 per 1000, rose again to 19·7 during the week ending April 11th, but was slightly below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 12·1 in Paisley and 13·0 in Aberdeen, to 21·8 in Leith and 27·4 in Perth. The 576 deaths in these towns included 29 which were referred to whooping-cough, 20 to measles, 17 to diarrhœa, 12 to "fever," 7 to diphtheria, 6 to scarlet fever, and not one to small-pox. In all, 91 deaths resulted from these principal zymotic diseases, against 52 and 61 in the two preceding weeks. These 91 deaths were equal to an annual rate of 3·1 per 1000, which almost corresponded with the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 21 in each of the two preceding weeks, rose to 29 last week, of which 18 occurred in Glasgow, 4 in Edinburgh, 3 in Aberdeen, and 3 in Paisley. The deaths from measles, which had been 6 and 8 in the two preceding weeks, further increased to 20 last week, and included 9 in Glasgow and 5 in Dundee. The deaths referred to different forms of "fever," which had been 4 and 6 in the two preceding weeks, further rose to 12 last week, of which 7 occurred in Glasgow and 2 in Edinburgh. The 7 fatal cases of diphtheria also showed a further increase upon recent weekly numbers, and included 3 in Glasgow. The deaths from scarlet fever, which had been 6 and 5 in the two preceding weeks, were 6 last week, of which 3 occurred in Edinburgh and 2 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 107 and 87 in the two preceding weeks, rose again to 110 last week, but were 51 below the number in the corresponding week of last year. The causes of 40, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·8 and 25·5 per 1000 in the two preceding weeks, declined to 25·4

Digitized by Google

during the week ending April 11th. During the thirteen weeks of last quarter the rate of mortality in the city averaged 25·3 per 1000, the rate during the same period being 19·5 in London and 17·7 in Edinburgh. The 170 deaths registered in Dublin during the week under notice were within one of the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against 7 and 8 in the two preceding weeks; of these, 4 resulted from diarrhœa, 2 from scarlet fever, and 1 each from small-pox, diphtheria, whooping-cough, and "fever." These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 4·1 in London and 2·8 in Edinburgh. The fatal cases of diarrhœa, which had been 3 and 2 in the two preceding weeks, were 4 last week. The 2 deaths referred to scarlet fever, corresponded with the number in each of the 2 preceding weeks. The 170 deaths in Dublin last week included 20 of infants under one year of age, and 44 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the numbers recorded in the preceding week. Two inquest cases and 4 deaths from violence were registered; and 76, or more than a third, of the deaths occurred in public institutions. The causes of 12, or more than 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-MAJOR KEAYS has been posted to Limerick and Surgeon-Major Harran to Cork. Surgeon-Major Dugdale and Surgeon-Captain Daly have embarked for Egypt. Surgeon-Major Adams has been appointed to the Thames District. Surgeon-Captain Gray has been posted to the South-Eastern District and Surgeon-Captain Brown to Cork. Surgeon-Lieutenant Probyn has joined at Chatham, Surgeon-Lieutenant Statham at Edinburgh, Surgeon-Lieutenant Cooper at Canterbury, Surgeon-Lieutenant Brereton at Portsmouth, Surgeon-Lieutenant Forrest at the Curragh, and Surgeon-Lieutenant Grattan at Athlone. Surgeon-Lieutenant Hooper is appointed to the Coldstream Guards in succession to Surgeon-Lieutenant French, transferred to the North-Western District.

ARMY MEDICAL STAFF.

Surgeon-Major-General John Colahan, M.D., is placed on retired pay. Surgeon-Lieutenant-Colonel James Coats, M.B., retires on retired pay. Surgeon-Captain William Henry Bean, half-pay, retires from the service receiving a gratuity.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Major R. R. H. Whitefield has been appointed Civil Surgeon of Patna; Surgeon-Major A. Tomes to act as Civil Surgeon of Howrah; Surgeon-Captain F. C. Clarkson to act as Civil Surgeon of Midnapur; Surgeon-Captain H. W. Pilgrim to act as Civil Surgeon of the 24th Parganas, and also to act as Medical Inspector of Emigrants (Colonial Emigration). Surgeon-Captain D. M. Moir is appointed to act as First Resident Surgeon, Presidency General Hospital; Surgeon-Captain E. O'Kinealy to act as Second Resident Surgeon, Presidency General Hospital; and Surgeon-Captain R. Bird to be Resident Medical Officer of the Medical College Hospital, Calcutta. Surgeon-Captain W. C. Vickers, M.B., C.M., to be District Medical and Sanitary Officer, Kistna, vice Surgeon-Lieutenant-Colonel A. J. Sturmer, appointed Surgeon, Fourth District; and Surgeon-Captain P. C. Gabbett to act as Resident Physician, General Hospital. The following promotion is made, subject to Her Majesty's approval:—Surgeon-Lieutenant-Colonel to be Brigade-Surgeon-Lieutenant-Colonel; Andrew Deane, M.D., vice Brigade-Surgeon-Lieutenant-Colonel Henry Black Purves, retired; Brigade-Surgeon-Lieutenant-Colonel William Price, M.D., Indian Medical Service (Madras), Principal, Medical College, Madras, and Senior Medical Officer, General Hospital, Madras, retires from the service subject to Her Majesty's approval.

NAVAL MEDICAL SERVICE.

Fleet-Surgeon Robert Turner has been placed on the Retired List, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets.

The following appointments are notified: — Staff-Surgeons: Joseph Crowley, M.D., to the *Grafton;* John L. Aherne to the *Lion;* and John B. B. Triggs, M.B., to the *Active.* Surgeon Harold P. Jones to the *Grafton.*

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain William H. B. Crockwell to be Surgeon-Major.

YEOMANRY CAVALRY.

Northumberland (Hussars): Surgeon-Lieutenant A. Brumell to be Surgeon-Captain.

VOLUNTEER CORPS.

Artillery: 3rd Middlesex: Henry Walter Syers, M.D., to be Surgeon-Lieutenant. 1st Hampshire (Southern Division, Royal Artillery): Ernest Frederick Eliot, gent., formerly Surgeon-Captain, to be Surgeon-Lieutenant. 2nd Lancashire: Surgeon-Lieutenant-Colonel J. Johnstone resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement. 5th Lancashire: Surgeon-Lieutenant Douglas John Mayhew Bone is appointed Lieutenant. The Highland: Second Lieutenant George Geddes, M.B., is appointed Surgeon-Lieutenant. *Rifle:* 3rd Volunteer Battalion the Royal Fusiliers (City of London Regiment): Surgeon-Lieutenant W. Barter, M.D., to be Surgeon-Captain. 5th Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Lieutenant Michael Joseph Mahony is appointed Second Lieutenant. 2nd Volunteer Battalion the Lincolnshire Regiment: Surgeon-Lieutenant R. E. E. South to be Surgeon-Captain. 1st Volunteer Battalion the East Yorkshire Regiment: Francis William Fullerton, M.D., to be Surgeon-Lieutenant. 3rd Volunteer Battalion the Lancashire Fusiliers: Surgeon-Lieutenant J. T. Smith to be Surgeon-Captain. 1st Volunteer Battalion the Duke of Cornwall's Light Infantry: Surgeon-Lieutenant C. R. Lawrie to be Surgeon-Captain. 1st Nottinghamshire (Robin Hood): Surgeon-Lieutenant W. J. Sprott, M.D., to be Surgeon-Captain.

Royal Engineers: S. R. Dyer, M.D., late Captain, to be Surgeon-Lieutenant to the 1st London Volunteers, and not as stated in our previous issue.

THE ARMY MEDICAL STAFF IN INDIA.

It is well known that some of the authorities in India and the medical service of that country have for a long time been desirous of having the medical charge of the British force serving in India handed over to them in addition to that of the native army. If this were done there would no longer be two military medical services for India, the Army Medical Staff not going to that country in medical charge of the European regiments. The *Army and Navy Gazette* has called attention to the subject and states that a rumour to this effect must be acknowledged to have some foundation, adding that it is believed a scheme has actually been proposed by the authorities at home to those in India for the removal altogether of officers of the Army Medical Staff from India replacing them by officers of the Indian medical service. The scheme is not at all likely, however, to find favour with the present Commander-in-Chief in India or with the military authorities of the European army in that country. However popular and acceptable it would be to the Indian medical service it would be exactly the reverse with that of the British service. The object of the Home and Indian Governments is probably one of supposed economy in the first place, and in the second to have a restricted service for home and the colonies so as to vastly reduce the size of the army medical department and do away with, or materially lessen, the large amount of foreign service of which its officers complain so much at present. The British Government, no doubt, hopes to meet the difficulty of obtaining candidates for the Army Medical Staff by such a wholesale reduction, but a scheme of this kind would revolutionise the service and arouse, we imagine, an immense amount of opposition.

THE BEST BOOT FOR THE INFANTRY.

All interested in the health and comfort of our army will read with interest and pleasure the letter which we print below. Nothing tells so much against a soldier as to be badly shod, nothing makes his toil more arduous and his work less efficient. It does not necessarily follow that the article which wins a prize allotted from an academic point of view is found to be thoroughly efficacious in practical tests, but the boot worn by our troops in Ashanti seems

Digitized by Google

to have justified the prize awarded to it, and we hope the Adjutant-General will take note of the fact.

To the Editors of THE LANCET.

SIRS,—It really does appear that the Boot question for the Infantry soldier is nearly settled. The boot that won the prize for an Army Boot last year has been tested in Ashanti. Officers and men speak highly of its durability and suppleness. Will the Adjutant-General oppose the pattern? I am of opinion that all public servants in uniform should have a boot of the same quality, pattern, and price.

I am, Sirs, your obedient servant,
W. H. ALLSOPP, Lieutenant-Colonel.

Junior Carlton Club, April 13th, 1896.

MONTHLY AVERAGE TEMPERATURE OF THE AIR AT WADY HALFA.

	1894.			1895.		
	Max.	Min.	Medium.	Max.	Min.	Medium.
January	73·9	46·6	59·5	75 4	45 5	60·1
February... ...	77·2	52·3	63 5	84·7	49 8	66·5
March	88·0	56·1	71·1	91·4	56·6	73·4
April...	94·8	62·4	78·8	97·2	63·0	80·6
May	106·0	71·2	88·7	106·5	73·6	89·9
June...	107 6	75 9	91·4	107·0	73·6	90 3
July...	104·7	75·0	89·8	106·2	75·2	90·9
August	103 1	75·0	89·1	104·2	76·1	89 8
September ...	99·9	73·9	86 3	100·2	74·8	87·0
October	100 6	68·3	83·7	93 9	67·3	80 1
November ...	82 4	56 3	69 3	85·3	59·9	72·2
December ...	77·0	48·7	62·4	78·4	51·4	64 2

The mean temperature is calculated from the maximum and minimum of the twenty-four hours, together with observations taken at 9 A.M. and 9 P.M. These tables have been calculated from the weekly returns published by the Egyptian Sanitary Department, to which we may refer readers who may be anxious for more information regarding the climate of Upper Egypt. As the troops advance southwards the heat may be expected to increase, but that other factors besides proximity to the equator influence the temperature is evident from the subjoined table, which has been compiled from the same sources as the other. Wady Halfa, it may be mentioned, is as nearly as possible two and a half degrees south of Assouan.

MEAN TEMPERATURE OF THE AIR AT FIRST AND SECOND CATARACTS.

1894.	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.
Assouan	61·3	63·3	70·9	79·5	90·3	93·6	93·0	90·7	86 9	87·1	72 5	63·1
Wady Halfa ...	69·5	63·5	71·1	78·8	88·7	91·4	89 8	89 1	86·3	83·7	69·3	62·4

Unfortunately, the comparison between the two stations cannot be given for 1895 as the reports from Assouan are incomplete.

THE MATABELE RISING.

The situation in Matabeleland is assuming a grave aspect. Sir Hercules Robinson has arranged to send an Imperial force of cavalry and some mounted infantry into that district as an addition to the volunteers and police force already there. It is thought locally that Sir Hercules Robinson was nevertheless right in advising that reinforcements from this country were not necessary, at any rate at present, as a large number of men accustomed to field service could be easily raised in the country. The fighting has been pretty severe and a number of men of the Colonial forces have been killed and wounded. The Hon. M. Gifford and the wounded generally are reported as doing well. There is a widespread rising of the Matabeles; the white settlers are exposed, of course, to a good deal of danger; and it seems highly probable that reinforcements will have to be sent from this country.

REORGANISATION OF THE INDIAN MEDICAL SERVICE.

A very important notification regarding the new reorganisation of the Indian Medical Service proposed by the Governor-General in Council has been published with the sanction of the Secretary of State for India, and the new scheme is to take effect from the 1st inst. The Medical Services of Bengal, Madras, and Bombay are now amalgamated in one service under the direct administrative control of the Government of India, with a Director-General as head of the amalgamated Indian Medical Service, together with other changes in the direction we indicated last week.

ASHANTI HONOURS.

The Queen has been pleased to give directions for the following appointments to the Most Distinguished Order of St. Michael and St. George, in recognition of services rendered in the recent expedition to Ashanti. To be Ordinary Members of the Third Class, or Companions of the said Most Distinguished Order: — Surgeon-Lieutenant-Colonel Montgomerie Blennerhassett and Surgeon-Major Edmond Munkhouse Wilson.

THE REGULATIONS FOR ADMISSION INTO THE ARMY MEDICAL STAFF.

We recently adverted to, and briefly commented upon, the proposed changes in the system of examination for admission into the Army Medical Service. These changes have since been embodied and published in an Army Order. They are in the direction we have already indicated and mainly with the view of strengthening the examination in medicine and surgery and putting other subjects in a relatively subordinate position.

THE PLAGUE AT HONG-KONG.

According to the latest telegraphic intelligence from Hong-Kong to the Colonial Office sixty-seven cases of bubonic plague occurred in the week ending 14th instant, making 482 cases altogether since the beginning of the year. The disease seems to be confined to the natives, no cases having so far been reported among the European residents.

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the Directors of the Naval Medical Supplemental Fund, held on the 14th inst., Inspector-General T. Russel Pickthorn in the chair, the sum of £55 was distributed among the several applicants.

Correspondence.

"Audi alteram partem."

THE WRITTEN AND UNWRITTEN LAW OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON.

To the Editors of THE LANCET.

SIRS,—The question of advertising by medical men has been much before the public both in the medical and general periodicals of late. There is a resolution of July 27th, 1882, of the Royal College of Physicians of London relating to this matter which reads as follows: "That the system of extensively advertising medical works and the custom of giving, whether for publication or not, laudatory certificates of medicinal and other preparations or of medical or surgical appliances is misleading to the public, derogatory to the dignity of the profession, and contrary to the traditions and resolutions of the Royal College of Physicians." Would you kindly inform me where these "Traditions and Resolutions" are to be found that I may be able to read the subject?

I am, Sirs, yours faithfully,
S. LEONARD CLIFT, M.R.C.S. Eng., L.R.C.P. Lond.

Church-road, Bournemouth, April 16th, 1896.

*** The word "Traditions" almost conveys the answer to our correspondent's question. The greater part of the law of the Royal College of Physicians of London is *unwritten*, consisting only of well recognised traditional principles and their application to particular circumstances. No attempt has ever been made to reduce these principles to a code, and we think that such an attempt would be of doubtful wisdom, as it would considerably fetter the operations of the College and lower its dignity simultaneously. But the College is not without a form of written law. Its authority in matters of professional conduct is wielded by the Censors' Board, and

Digitized by Google

the proceedings of this Board as embodied in the minutes and read at each quarterly meeting of the College constitute a very important collection of decisions. Certain By-laws, again, have been enacted from time to time by the College to define a line of conduct in particular contingencies, of which those at present in force may be found in Chap. XXVI. of the *By-laws and Regulations of the College*, a copy of which may be had on application to Mr. Fleming, the bedell, at the office of the College. Lastly, certain Resolutions of the College, passed generally on the recommendation of the Censors' Board and aimed at some growing offence against professional honour and good manners, have been printed and a general currency given them. It is such a Resolution that our correspondent has quoted, and it was passed by the College on July 27th, 1882.—ED. L.

MATERNAL SYPHILIS.

To the Editors of THE LANCET.

SIRS,—Many of the difficult questions connected with syphilis and maternity are dealt with in Dr. Coutts's able and interesting Hunterian Lecture in THE LANCET of April 11th. Quite unaware of Dr. Coutts's lecture and views I submitted to you a paper on the same subject on March 25th, approached rather from the gynæcological side, in which I ventured to remark on the prevalence and manifestations of syphilis in married women subsequently to abortion or delivery, and I attempted to urge the primary origin of syphilis in the mother rather than the "paternal syphilis" of the fœtus with "syphilis by conception" in the mother. Dr. Coutts states that "all observers are agreed in the fact that a very large proportion of the mothers of syphilitic infants exhibit no outward evidence of the complaint even after prolonged and careful search." Dr. Coutts mentions 100 mothers who showed manifestations and 100 who were *apparently* free from syphilis. This percentage agrees with the figures of Mr. J. Hutchinson, who also has stated: "It is exceptional for such mothers to suffer from ostensible syphilis." Such statements as these have considerably perplexed me, for while I have been willing to admit apparent immunity in the mothers of syphilitic children brought to children's hospitals, I have been very much struck with the constant and spontaneous complaint of mothers who in gynæcological practice attribute their ill-health to abortion or confinement with no history of previous illness. Such complaints may be classed as debility, general ill-health, severe headaches, loss of or thinning of hair, sore throats, eruptions, palmar psoriasis, subinvolution and prolapse, leucorrhœa and hyperæmia of the vaginal mucous membrane, menorrhagia, erosions of the os, endometritis, chronic ovarian and tubal disease, and superficial sores of the anus and affections of the rectum. If these are not ostensible signs of syphilitic infection they in many cases are a sequel to a syphilitic pregnancy, while gummata, as in Charrier's case, and diseases of the bones and nervous system are by no means uncommon in married women in whom no suspicion of syphilis has arisen, but who have been pregnant by a husband who has had syphilis in early life. I regret I am unable at present to give complete and comparative statistics; I am, however, indebted to Mr. Henry Lee for kind permission to make use of his case-books, and I have collected a sufficient number of cases myself to satisfy me that ill-health in women subsequently to a syphilitic conception is far more common than is supposed, and that the views of Charrier, Cullerier, Notta, and others, who hold that "every syphilitic child is born of a syphilitic mother," are worthy of greater clinical recognition. A. Fournier states, "Syphilis in the child nearly always implies syphilis in the mother"; while Mr. Hutchinson himself, in interpreting Colles' views, sets forth that immunity and syphilisation are synonymous, and that the possibility of later manifestations cannot be excluded. Moreover, the works of Diday, Tyler Smith, and L. Parker clearly demonstrate the importance and recognition of syphilis in the mother subsequently to a syphilitic conception. If a mother is thus capable of being infected, it is obvious that the power of transmission to the offspring outlasting that of direct infection of the mother is of small significance.

The theoretical explanation of syphilis in the fœtus and in the mother is possibly of second importance to the clinical recognition of syphilis in parous women. At the same time it is of such interest that it compels attention. I confess "paternal syphilis" and "syphilis by conception" do not satisfy me. The absence of primary disease in the mother applies to both paternal and maternal origin, for in nulliparous women primary disease may be so slight as to escape notice or altogether absent, while the lumbar glands may be enlarged and the inguinal glands normal. The absence of syphilis in the mother with manifest syphilis in the fœtus is not conclusive, for absence of manifestations in a mother who has contracted it in the usual way is, as Dr. Coutts notes, not impossible. While Dr. Coutts considers there is no proof of the attenuation of the syphilitic virus in the male I confess I lean to the primary syphilisation of the wife, with partial or complete immunity, till pregnancy disturbs such latency and manifestations result subsequently to abortion or delivery. The following points seem to support such theory: 1. It is no uncommon thing to find that intercourse and marriage lights up latent disease in men, and genital superficial lesions or modified urethritis appear. In a disease dependent on periodical activity of germs and production of antitoxin it seems almost unreasonable to doubt that the genital secretions of the male or the relapsing lesions of the penis are incapable of producing at a period of minimum activity syphilisation without obvious manifestations. 2. In a few cases that have presented themselves to me I have noted that pregnancy occurring in women who had previously suffered from syphilis, the syphilis which was latent was lighted up and manifested itself in ulcerated throat, genital sores, and eruption. 3. In pelvic absorption the extent of glandular distribution may considerably modify the virus and general infection.

The maternal origin of syphilis in the fœtus in every case appears to be more reasonable than that the spermatozoon possesses the ability to infect the fœtus and secondarily the mother. As regards this point I understand Dr. Coutts disbelieves, as I do, in "syphilis by conception," but I do not follow him when he admits immunity by conception, partial or complete, which I take it, is syphilis by conception. One other point I would like to touch on in Dr. Coutts' valuable lecture. He explains Diday's "law of decreases" by immunity gained by the evolution of some chemical principle or antitoxin antagonistic to the growth of the germs. That is one explanation of immunity in general, but I hold strongly to the theory of elimination of syphilis through the skin and secretions, and beg to quote Dr. J. F. Payne in his manual of General Pathology: "It is one of the oldest traditions in medicine that diseases which produce an exanthematous eruption are thrown off by the skin, which, expressed in modern language, means that the poison, or micro-organism, is eliminated by exfoliated epidermis and by the cutaneous secretions. Considering the case of syphilis, there is nothing impossible or even improbable in this theory." I am, Sirs, yours faithfully,

JOHN A. SHAW-MACKENZIE, M.D. Lond., &c.,
Formerly Registrar to the Victoria Children's Hospital, and late Pathologist and Physician to the Out-Patients,
April 13th, 1896. Chelsea Hospital for Women.

THE ETYMOLOGY OF MEASLES.

To the Editors of THE LANCET.

SIRS,—Dr. William Sykes, in a learned paper on the Origin of English Disease Names,[1] which will have been read with general interest, has, in following Professor Skeat as to the derivation of "measles," taken up a position which I had already shown[2] to be untenable. Trench, in his "Select Glossary," had derived measles from the mediæval Latin *miselli*, diminutive of *miser*, meaning the leprous, although he did not explain how measles came to be associated with leprosy. Professor Skeat, in his "Etymological Dictionary," did not doubt—it is, indeed, beyond doubt—that *miselli* reappears in the Norman-French form of mesels, or mesles, or mezeals; but he rejected Trench's etymology of measles on the ground that it is not the same word as mesles. "The spelling with the simple vowel *e*," he says, "instead of *ea* or *ae*, makes all the difference. The confusion between the words is probably quite modern." This bland assertion, improbable on the face of it, seeing that it relates to so inconstant a thing as spelling, has sufficed for Dr. Sykes, who thereupon pronounces

[1] THE LANCET, April 11th, 1896.
[2] History of Epidemics in Britain, vol. i., p. 632, 1893.

Digitized by Google

me to be "probably in error," as well as "dogmatically" so, in defending the old derivation of Trench and in making it intelligible by showing that Gaddesden had actually grouped the small spots of morbilli with the broad, dusky red spots on the legs of *pauperes et consumptivi*, who were called "anglicè *mesles*." I had already shown that the separation in orthography between mesles and measles asserted by Professor Skeat had no existence. Four English writers of the Tudor period—Pace (in a letter of 1518), Skene, Cogan, and Lodge—use the forms mezils, mesillis, or mesels, where they mean morbilli; while four others—Elyot (1541), Phaer, Clowes, and Kellwaye—write the word with *ea*, or in the way that has become fixed by subsequent usage. There was no uniformity: how could anyone look for it? Again, in the printed text of Shakespeare (who spelt his own name in five different ways) we find, "Those meazels which we disdain should tetter us" (*Coriolanus*; Act IV., Sc. 1), meaning a scurvy rabble, such as the mesells or lazars or beggars in the "Vision of Piers the Ploughman," of whom Professor Skeat was doubtless thinking. There was, in fact, only one word, with the usual latitude of spelling, still used occasionally in its original sense as late as the time of Shakespeare, but in its common use diverted to the meaning which Gaddesden's reference to it as a larger form of morbillous spots, in his chapter "De Variolis et Morbillis," had opened the way for. His "Rosa Anglica" had great authority for more than two centuries, and was printed almost as soon as printing began, so that it is not difficult to understand how mezils, or mesles, or meysyls, or measles should have got that specific meaning of morbilli which we find it to have about the beginning of the Tudor period. The first mention of an epidemic under that name which I have noted is under the date of January, 1483, a certain infirmity then reigning, as was said, in Canterbury—namely, le meysyls, by reason of which the King did not accompany the Queen into the city. Dr. Sykes thinks that I had erred, as he supposes, by taking a too exclusively English standpoint in examining "the literature of the subject," meaning that I had paid no heed to the dictionary derivation of measles from the Dutch *maeseln*. But how can one's point of view be too exclusively English when we discover the very fountain and origin of this English medical term in a freak of classification by Gaddesden? Measles having been shown to be the same word as mesles, the association of the latter with morbilli in the "Rosa Anglica" surely determines our priority over the Dutch.

I am, Sirs, yours faithfully,

C. CREIGHTON.

Great Ormond-street, London, W.C., April 13th, 1896.

MIDWIVES' REGISTRATION.

To the Editors of THE LANCET.

SIRS,—We trust you will allow us to remind those members of the profession who are in favour of the education, registration, and supervision of midwives that a Bill for securing these objects has been set down for reading in the House of Commons on May 6th. We desire to point out that no time should be lost in bringing the question under the notice of Members of Parliament and putting the case for legislation fairly before them. We are aware that a number of our brethren are opposed to such legislation, but we know also, and we think it very important that Members of Parliament should know, that a very considerable number are in favour of it. The object of this letter is to urge the advocates of legislation to give their active support to the present Bill, which is identical with the amended Bill of Lord Balfour of Burleigh, introduced and read a second time in the House of Lords last year. We are, Sirs, yours faithfully,

ROBERT BOXALL, M.D. Cantab., } Hon. Secs., Midwives'
ROWLAND HUMPHREYS, } Registration Association.

Fellows-road, N.W., April 13th, 1896.

To the Editors of THE LANCET.

SIRS,—In your issue of April 4th your Liverpool correspondent calls attention to the threatened dismissal of the visiting staff of the Liverpool Lying-in Hospital and to the appointing of midwives in their stead. This is a speedy nemesis, and should open the eyes of all practitioners who are in favour of the so-called registration of midwives. For some years the medical staff of this hospital has lectured and granted elegant diplomas to midwives. It has also stood by and allowed their district midwives to attend, on their sole responsibility, all out-door confinements, and without the aid of the district medical staff. Why, then, it is asked, can the visiting medical staff take valid objection to the plan being put into force in connexion with women confined in their hospital—which is, and has been, in force with their approbation among the home patients? Consistency of conduct is a valuable weapon, and it being forgotten is likely to recoil some day upon those who lay it aside. I do not, however, wish to blame unduly the visiting medical staff; I wish to use it as an illustration of the true and ulterior motives of the supporters of midwives registration. Thus Mr. H. C. Burdett suggested that no resident medical officer should be employed in small lying-in hospitals, but that his place should be taken *by a midwife*.[1] This excludes resident medical officers. The committees of the City of London Lying-in and of the British Lying-in will not allow medical students to be trained in these hospitals in midwifery. This excludes medical students. In March, 1895, the Leicester board of guardians tried to appoint a midwife to take the place of their district medical officer, but the Local Government Board would not allow it. This proposed to do away with the district medical officer's conducting pauper confinements. In November, 1895, the Peterborough guardians ("guardians" of the poor in inverted commas) sent a circular letter to all the other Poor-law guardians in England asking them to resolve: "That the members of the board are of opinion that it is desirable that boards of guardians shall have discretionary power of appointing duly qualified midwives for attendance at childbirth *in place of the district medical officer*, subject to the condition as laid down in the Poor-law Board's Circular, No. 88." A most modest suggestion for those who should be *the real* guardians of sick women and infants! In the Hospital Annual, 1891, Mr. Burdett again writes: "It behoves all midwives just now to be sure of obtaining a good certificate. ..... *Every reason which was brought forward for the registration of medical men applies also to midwives.* ....." Another modest remark! Dr. W. Grigg, lecturer to pupil midwives at Queen Charlotte's Hospital, said: "I am sure you will agree with me in hoping the day is not far distant when all midwifery will again fall into the hands of women." Why, I ask, should the lying-in room of the poor be again made the first stage to the chamber of death? The Midwives Institute, in its prospectus, modestly states: "As some confusion exists in the public mind as to the difference between midwives and monthly nurses, it may be well to state that a midwife is qualified to attend all cases of natural labour—that is, she undertakes the cases herself *without a doctor, and is, in fact, engaged instead of one.*"

I think, Sirs, the above quotations show clearly that the promoters of this iniquitous Bill propose (*a*) to exclude medical students from lying-in hospitals for training; (*b*) to exclude all resident medical officers; (*c*) to exclude all visiting medical staffs; (*d*) to exclude the district Poor-law medical officers from attending Poor-law confinements, and (*e*) generally to degrade and prostitute the Medical Act, 1886, and to revert to those death-dealing times when midwifery was an occupation of the uneducated and dangerous. At least thirteen women die each day in England in childbed. Is not this sad and disgraceful death-rate—not to mention the sick and maimed rates—sufficient to prompt us to insist on the elevation of the practice of midwifery to a much higher level than it occupies to-day, and to do everything to prevent its degradation and retardation?

I am, Sirs, yours faithfully,

Liverpool, April 15th, 1896. ROBERT R. RENTOUL.

"THE EFFECT OF MUSCULAR WORK UPON THE ALKALINITY OF THE BLOOD."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of April 11th (p. 1020) Mr. Fotheringham contrasts a statement of mine in THE LANCET of March 7th (p. 611) with one in the paper by Dr. Hutchison which follows it, and asks, "Which is the correct view?" I reply that probably both are correct, as their opposition is apparent rather than real. The conclusion I draw from my facts and figures (p. 614) is "that the effect of exercise is to increase the function of urea," and as I have pointed out in my book that the excretion of urea and of acid in the urine

[1] See Pamphlet, No. viii., 1888, Hospitals Association.

Digitized by Google

generally rise and fall together, it follows that the effect of exercise is to raise the acidity of the urine and diminish the alkalinity of the blood. And my Figures 1 and 2 (p. 611) show that while there is at first a fall of urea and acidity, this is followed by a rise that more than makes up for the fall, so that the total effect of the exercise is to raise the acidity of the urine and probably to diminish the alkalinity of the blood; and Dr. Hutchison points out (p. 616) the correspondence between the increase of the blood's alkalinity after meals and the appearance of the "alkaline tide" in the urine, and he adds, "The latter is to be regarded as the expression and result of the former." Mr. Fotheringham's statement that my entire theory of the cause of fatigue rests on the assumption that the effect of exercise is to increase the alkalinity of the blood is only half the truth, as my thesis is that fatigue is the result of the defective capillary circulation which excess of uric acid in the blood produces, and that if the uric acid has not been introduced (vegetarianism) or has been previously cleared out by solvents the alkalinity of the blood is a matter of no consequence. But, as is above shown, and as Mr. Fotheringham will find further reasons for believing in my book, the changes in the acidity of the urine are to a certain extent good and reliable indices of the corresponding changes in the alkalinity of the blood.

I am, Sirs, yours faithfully,

Brook-street, W., April 14th, 1896. ALEXANDER HAIG.

"THE DUTIES OF DIVISIONAL SURGEONS IN CASES OF INFECTIOUS DISEASES."

To the Editors of THE LANCET.

SIRS,—Dr. W. Thyne complains that my letter is no answer to his inquiry and that I admitted two flagrant breaches of professional etiquette. I beg to differ with him. I have done nothing of the kind, as I fail to see that I have done anything unprofessional. Dr. Thyne adduces several other instances of similar misconduct occurring in his practice. He says some months ago scarlet fever attacked several families of the police force. "In one instance the divisional surgeon ordered the family out in the garden at the end of a fortnight (at least, so the mother told me). I was also told that the inunction of a medicament which I ordered had not the sanction of his approval. In another case the divisional surgeon got the patient out of bed in order to examine his throat." To the above charges I simply have to say that they are totally untrue. With the exception of the two cases mentioned in his letter of March 21st, I have not seen any case of infectious disease amongst the families of the police for sixteen months in which he has been the medical attendant. Dr. Thyne also says that other divisional surgeons whom he had consulted disclaim any mission to offend professional propriety. I quite agree with them on that point; I had none when I had the whole of my brother practitioners to work with; but now I have a gentleman to contend with who degrades his profession, who undersells his brother practitioners by taking away their private patients and offering to attend a whole family for 2½*d.* per week, against 6*d.* paid by all the other clubs in this town. Notwithstanding Dr. Thyne's threat to report me to Mr. Mackellar, the chief surgeon, I can assure him I have no malice towards him and that when he gives up his ½*d.* fees divisional surgeons and his fellow practitioners will be delighted to show him all the courtesy that is due to him as a gentleman and a professional man.

I am, Sirs, yours faithfully,

W. J. HARNETT, F.R.C P. Edin., D.P.H.,

Barnet, April 14th, 1896. Divisional Surgeon, Barnet.

*** This correspondence must now cease.—ED. L.

DR. BOUDET DE PÂRIS' "STÉTHOSCOPE AMPLIFICATEUR" AND THE PHONENDOSCOPE.

To the Editors of THE LANCET.

SIRS,—I have been somewhat surprised to notice that although the phonendoscope has been for some time before the public and a detailed description of it appeared in the columns of THE LANCET of Feb. 29th, no one has thought fit to point out that it is simply a modification, and I may say a very trifling one, of a stethoscope that has figured for years in a French catalogue. It is true that the precursor of the phonendoscope would seem to be as little known in its native country as in England, for a high clinical authority to whom I showed it recently, pointing out the identity of the two instruments, at first supposed I was attempting to vindicate the claims of an English inventor. The *Comptes Rendus de la Société de Biologie* of March 6th contain, moreover, an account of a demonstration given there by Dr. Bianchi, with cuts of his instrument and figures illustrating the localisation of organs by a *new method* of investigation, and no one appears to have had a word to say as regards priority. If any excuse beyond that of doing justice to one who is no more is necessary for raising this question, I may say that personally I owe a kind of debt of courtesy to the late Dr. Boudet de Pâris which I am thus enabled to discharge, although fifteen or sixteen years ago I called attention to the antecedent claims of another person when he invented his electric diapason.

Dr. Boudet de Pâris invented a number of instruments for studying the sounds of the heart and arteries, all of which may be found in the catalogue of C. Verdin, the well-known maker of philosophical apparatus—the sphygmophone, the cardiophone, the micro-stethoscope, and the "stéthoscope amplificateur à membrane d'ébonite." The first three, as well as a myophone, have electrical transmission of the sound from a microphonic receptor to a telephonic ear-piece, but the "stéthoscope amplificateur" is practically the phonendoscope. The only difference is in the shape and the arrangement of the membrane, which, I venture to think, is better in "Boudet's stethoscope." Dr. Boudet de Pâris' stethoscope consists of a hollow cone with a membrane or plate fixed about half an inch from the open base; there is a stem as in the phonendoscope, which can be brought into play when fine localisation is desired by a screw. When the stem is screwed away from contact with the skin the instrument is the same as the phonendoscope without the second plate, which is removed when the stem is not employed. Boudet's stethoscope appears to me superior in that the vibrating membrane is more perfectly insulated from any sound except that which comes from beneath the portion of skin enclosed by the rim of the chest-piece.

Dr. Bianchi speaks of a new method of mapping out organs by his instrument, and the same *Comptes Rendus* gave diagrams showing the position of the liver, spleen, kidneys, and other organs. The effect of drinking on the contour of the stomach is shown with a precision that reminds one of the diagrams of modifications of heart dulness lately published by Schott's pupils. The following is the *modus operandi*. The button-shaped end of the stem is placed on the organ to explore and the vicinity stroked gently "as if smoothing ruffled fur." The stroking may be centripetal, centrifugal, or parallel to the contour Whilst on the organ a rough sound is heard; when its limit is reached the timbre suddenly changes. One lobe of the lung may be differentiated from another, and one cavity of the heart from the other, the exact line of the intraventricular septum determined, &c. I will not discuss the possibility of these delicate delimitations, but here again, Is Dr. Bianchi right in presenting the method as his own? There is not a word about any such mode of exploration in the prospectus which accompanied the phonendoscope two months ago, where it simply claims to be an intensifier of sound. Dr. Bianchi has, in my opinion, accidentally no doubt, re-invented a "stéthoscope amplificateur" which is not only identical in principle with that of its prototype, but, notwithstanding the difference of form, identical in amplifying power. There is only one difference between the two instruments, and that is not of intensity but of quality. For some acoustic reason the phonendoscope is clangorous and metallic. This would, perhaps, be of no importance in auscultatory percussion, as we are listening to sounds of our own creating and all that is required is distinctness; but in auscultation of sounds emanating from within the thorax we must be sure of having them transmitted without modification of their quality. In this respect "Boudet's stethoscope" is a much more perfect instrument, and it is most surprising to me that its existence should be so little known.

I am, Sirs, yours truly,

April 13th, 1896. OSCAR JENNINGS.

"THE QUESTION OF MEDICAL DEFENCE."

To the Editors of THE LANCET.

SIRS,—I was very glad to see Dr. Lovell Drage's letter in THE LANCET of the 4th inst., although, like yourselves, I do

Digitized by Google

not agree with his principal conclusion. I am fully in sympathy with the proposed enlargement of the powers of the British Medical Association, but should be sorry to see the absorption of the defence unions by this body. We know that these unions have hitherto done their work excellently well; we do not know that they would be equally efficient if merged in the larger association. It should be remembered that medical defence has a collective as well as an individual bearing. The latter is well looked after by the defence unions, but they do not touch the former, which concerns the defence of the whole profession in any particular locality against enemies from without—e.g., the societies trading in medical attendance—and foes from within—e.g., members of the profession who adopt reprehensible practices which yet may not be "infamous" in a legal sense.

The difficulty in constituting the British Medical Association a court of control is that it has not, and cannot have, any greater punitive power than expulsion from itself, which to many is no penalty at all. The corporations, however, have already very extensive powers, which the profession would gladly see increased if they became representative bodies. It is to them, therefore, that we should turn our attention, and I invite Dr. Drage and those who think with him to support the effort which is now being made to secure representation for the Members of the largest corporation of all, the Royal College of Surgeons of England.

I am, Sirs, yours faithfully,

April 12th, 1893. W. G. DICKINSON.

"SUBCUTANEOUS EMPHYSEMA OCCURRING DURING LABOUR."

To the Editors of THE LANCET.

SIRS,—As Dr. Moffat says in THE LANCET of March 28th the above is a somewhat rare accident. In January of this year a primipara whom I attended showed well-marked emphysema over the thorax, face, and neck. This appeared after the second stage of labour was over and disappeared in about six days. It is of interest to record that she had emphysema in the same regions during an attack of influenza some years ago. The labour was rather tedious and the forceps were used. During the labour the patient had several bad fits of coughing (due to bronchial catarrh), which may have been the direct cause of the subcutaneous emphysema.

I am, Sirs, yours truly,

April 13th, 1896. ALEXANDER INNES, M.B. Aberd.

PUBLIC HEALTH APPOINTMENTS AND THE "LOCAL" CANDIDATE.

To the Editors of THE LANCET.

SIRS,—The recent election of medical officer of health for Sunderland is but another example of the useless and irritating expenditure of time, money, and personal comfort into which busy sanitarians in important public positions are so often unnecessarily led by the specious advertisements of sanitary authorities. To corporations with no soul to save or body to kick the mere fact that a "local" candidate has declared his intention to face the starter is too often quite sufficient to ensure his success (be his merits or demerits what they may) against the most highly qualified "stranger." The applicants for the appointment in question included one of the recent temporary inspectors of the Local Government Board and the health officers of several large Lancashire and Cheshire towns, men of proved ability and administrative experience. The Council nevertheless, by an overwhelming majority, entrusted the health interests of 140,000 people in this notoriously typhoid-stricken town to the hands of an estimable general practitioner, possessing the necessary academic qualification, but virtually without further practical experience of the duties of such a post. Comment is unnecessary; but I may, perhaps, be permitted to suggest to the town councillors of Sunderland and to others similarly actuated that under such circumstances it would in future be more straightforward to include in their invitation for applicants a statement of preference for any legally qualified *local* candidate. Then medical officers of health who are unable to practise the Scriptural precept and gynæcological feat of being born again (the accouchement, of course, to take place in the town they desire) will only have themselves to thank for their failure there.

I am, Sirs, yours faithfully,

April 14th, 1896. SEMPER VIGILANS.

FEVER HOSPITALS.

To the Editors of THE LANCET.

SIRS,—The authorities of the London Fever Hospital are making large additions to their institution in Liverpool-road, presumably for the accommodation of an increased number of patients suffering from infectious diseases. The new wards will be within a few feet of my garden. Will you kindly inform me what public authority (if any) regulates the erection of such buildings, or can any person or number of persons build fever wards where they choose in London? Thanking you in anticipation,—I am, Sirs, yours obediently,

Gibson-square, Islington, N., April 7th, 1896. H. G. D.

*** We rather doubt the conclusion arrived at, having been informed that the governors of the hospital have decided to improve their ward accommodation and to pull down some of the existing buildings, hence we should not be surprised that, compared with the past, the accommodation provided will in the future be less rather than more than it was. As regards the "few feet" referred to, it will be remembered that the limit of ascertained safety adopted by the Local Government Board and all sanitary authorities for the treatment of infectious fevers other than small-pox is actually based on the long experience of the London Fever Hospital, where the buildings intended to receive infected persons and things stand 40 ft. from the boundary of the hospital site. With this 40 ft. it was found that even where the admissions of fever cases numbered 3000 a year no spread to the houses around occurred. We can hardly believe that the governors are departing from this settled precedent of safety. We believe that apart from an injunction no remedy would apply, but we should advise our correspondent to learn the actual facts by communication with the hospital authorities.—ED. L.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Death of Mr. George Holt.

IN the death from pneumonia of Mr. George Holt, head of the well-known firm of Lamport and Holt, Liverpool has lost a prominent citizen and University College, Liverpool, a true friend. One of the promoters of that foundation, he ever took the greatest interest in its success, which was substantially shown by his first subscription of £10,000 which was requisite to complete its equipment for incorporation in the Victoria University. It was in its medical school that he took a special interest, and his benefactions to it have been numerous. The chairs of Physiology and Pathology were endowed by him in the amount of £10,000 each, to which was added a further sum of £10,000, for the maintenance of laboratories in those branches of investigation. In addition to these benefactions he presented its medical faculty in 1886 with the sum of £2000 for distribution during the ten succeeding years in tutorial scholarships of the value of £100 each. These have been of the greatest service to industrious students in affording them opportunities for research in special departments of the medical school which otherwise might not have occurred to them. He further fitted up in a complete manner Ashton Hall as a pathological and bacteriological laboratory which is one of the most complete of its kind in this country. Besides providing accommodation for the teaching of morbid anatomy, pathological chemistry, and bacteriology, provision is also made for private investigation in pathology. This building further contains the museums of hygiene and materia medica. This does not exhaust the list of his benefactions; a further sum of £1000 was given as a donation to the college library, to be expended in annual instalments of £100. He was also a generous contributor to the maintenance fund of the college and a warm friend of education in general. Indeed, it is probably as a benefactor of University College that his name will live longest in local memory. He presided at the annual meeting of the Royal Infirmary on Jan. 30th, looking the picture of

Digitized by Google

health, and on his retiring from the chair unostentatiously presented the funds of that charity with the handsome donation of 500 guineas. A large and representative attendance at the funeral testified to the esteem in which he was held by all classes.

Glanders in Liverpool.

At the weekly meeting of the Health Committee, held on the 9th inst., attention was drawn to the alarming spread of glanders among horses in Liverpool. Both the medical officer of health and the veterinary superintendent, it was stated, were desirous of taking drastic measures, since the disease was serious not only to horses but to men also. In one stable seven horses had to be killed. It was urged that the committee should approach the Board of Agriculture on the subject, as it was necessary to have further powers. A member stated that at present horses were sent out from infected stables to work without restriction throughout the city and to drink at the same troughs as other animals. Alderman Bligh mentioned as within his own experience a fatal case of glanders contracted by a woman from a diseased horse, and felt, with other members, that it was absolutely necessary that the committee should have some powers of quarantine. A special committee was appointed to inquire into and to report on the matter, with power to wait as a deputation on the Board of Agriculture and on the Lancashire County Council. The deputation, consisting of two aldermen and two members of the city council together with the medical officer of health and the veterinary superintendent, proceeded to London on Monday to wait upon the Board of Agriculture and to confer with the officials of the London County Council as to the best means of stamping out the disease.

Liverpool Workhouse Extension.

The limited accommodation in this workhouse for able-bodied paupers has long been a subject of anxiety to the guardians of the parish. Several schemes have been suggested for relieving the pressure on the available space. At the last meeting of the select vestry the recommendations of a special committee appointed to consider the matter came up for discussion. The chairman moved the adoption of the report, which recommended that a site of not less than thirty acres be secured within easy access of the parish, and that on it should be placed a thoroughly equipped asylum for the bedridden and infirm; that the existing buildings at Kirkdale (which are now used as schools), with such slight alterations as circumstances might require, should be utilised as a relief workhouse for healthy inmates, and that the large building on Brownlow Hill, in which there are now upwards of 1000 medical and surgical cases besides infirm and able-bodied paupers, should be used as a hospital. He also pointed out that there are now 1000 more inmates in the workhouse than there were ten years ago. Upon a vote being taken the recommendation of the special committee was rejected. A resolution was afterwards carried that pavilions be erected in front of the Kirkdale site to provide for the sick poor now located in the attic wards. It may be mentioned that this huge workhouse contains about 4000 inhabitants.

Success of Liverpool Medical Students.

At the recent examination for the final M.B. Victoria seven candidates from University College, Liverpool, presented themselves. Six of these were successful, two obtaining first class, and one second class, honours. The fact of all the honours being carried off by Liverpool students has given great satisfaction here, and is an indication of the rapid strides which this school has made since the endowment of the chairs of anatomy, physiology, and pathology, so ably filled by Professors Paterson, Sherrington, and Boyce. All these gentlemen have been unwearied in their efforts to bring the Liverpool School of Medicine well to the front.

Birkenhead Medical Society.

The annual dinner of this society was held on Saturday evening last, under the chairmanship of Dr. Harris, J.P., the President of the society. The dinner, which was of a *recherché* character, was enlivened by a delightful musical programme. Dr. Harris made an excellent chairman, and under the influence of his geniality of manner and witty speeches the evening passed off in a most enjoyable manner.

April 15th.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Sad Death of Mr. John Miller Kirkman.

A VERDICT of suicide whilst temporarily insane was returned by the coroner's jury at the inquest held on April 9th upon the body of Mr. John Miller Kirkman, M.R.C.S. Eng., L.R.C.P. Edin., of Wootton Bassett, near Swindon, who committed suicide by cutting his throat with a razor and then taking hydrocyanic acid at Wootton Bassett on April 7th. Mr. Kirkman, who had lately complained of being overworked, should have attended the Quarter Sessions at Salisbury held on that day to give evidence in the case of a labourer at Swindon who was charged with attempting to commit suicide by cutting his throat. Much regret is felt by the inhabitants of Wootton Bassett, for Mr. Kirkman was a well known and much esteemed resident, extremely popular, and identified with all movements for the good of the town.

The Hospital Saturday Fund at Bristol.

The Mayoress of Bristol has lately received the ladies associated with the various hospitals of Bristol for the purpose of making arrangements for the successful working of the proposed Hospital Saturday. It was agreed that there should be a house-to-house canvass, as well as a street collection, and in order to carry this out efficiently a ladies' committee was appointed. It was thought that the villages round Bristol, which send many cases to the infirmary and hospital, should be included in the sphere of operations. The Hospital Saturday will in all probability be held in June. The Bristol people have of late had their attention called to the urgent need of their two great medical charities for increased support, for in spite of strict economy the committees of the Royal Infirmary and General Hospital have found their expenditure considerably exceed the annual income. Under these circumstances it is desired to make this year's Hospital Saturday productive of substantial results.

Lunacy in Somerset.

The visiting committee of the Somerset and Bath asylum, in their annual report, which was read at the quarterly meeting of the Somerset County Council held on April 7th, stated that the number of patients on the 31st of March, 1896, was 349 males and 522 females. There were 182 persons boarded out, 60 being at the Bristol City Asylum. The total number of patients, including those boarded out, was 1053, an increase of 24 over that on the same date last year. The patients at Wells were considerably in excess of the accommodation. The overcrowded state of the asylum rendered the administration difficult and hindered the medical treatment of the patients. The expenditure on account of the Western Joint Asylum was £81,168. It is hoped that there will be accommodation for 200 patients at the commencement of the new year in the new asylum.

The Jenner Society.

At the meeting of the Gloucestershire Standing Joint Committee held on April 7th the chairman (Sir J. E. Dorington) laid before the committee Dr. Bond's proposal to form a Jenner Society, and said that the only way to check the dissemination of mischievous views which were contrary to all scientific knowledge was by putting the public right, and it was proposed with this object to start a Jenner Society in Gloucestershire which they hoped might spread throughout England and counteract the mischief wrought by the Anti-Vaccination Society. The Lord-Lieutenant (Earl of Ducie) was willing to become president, the Dean of Gloucester chairman of the executive committee, with Mr. Lloyd Baker as honorary treasurer and Dr. Bond as honorary secretary, and he hoped a good start would be made that day and that they would get members in Bristol and Cheltenham and grow to be a great society. Twenty-one gentlemen had already signed as willing to become members. The vice-chairman and several other gentlemen expressed themselves as thoroughly in sympathy with the proposition. The chairman also said that three cases of small-pox had occurred in the county asylum, where there were over 1000 patients and nearly 200 attendants, but the whole of the patients and attendants were at once vaccinated, and the disease was stayed.

The University College of South Wales and Monmouthshire.

The total subscriptions promised up to the present for the

Digitized by Google

new building fund of the University College of South Wales and Monmouthshire amounts to over £16,000. This is a most encouraging response to the appeal which was recently made at a public meeting, but as the condition of the Treasury has to be fulfilled by July next there still remains a considerable sum to be collected. Mr. Louis Tylor, the treasurer of University College, confidently anticipates that this sum will be raised. The Treasury has authorised the payment of £10,000 to the building fund, this being half the sum promised by her Majesty's Treasury on condition that £20,000 was collected in South Wales and Monmouthshire.

Death of Mr. David Thomas of Llandovery.

Mr. David Thomas, J.P., M.R.C.S. Eng., L.S.A., died at his residence, Mile End House, Llandovery, Carmarthenshire, on March 31st, in his eighty-second year. Mr. Thomas took the qualification of M.R.C.S. in 1838, and the L.S.A. a year later. Deceased, who was extremely popular in the town, had retired from practice for some years. He had been connected with the Llandovery Corporation for many years, and at one time filled the office of mayor. Mr. Thomas was formerly assistant surgeon to the Royal Carmarthenshire Rifle Volunteers, and was a justice of the peace for the county. The funeral took place on April 4th, at Llandingat Church, Llandovery, amidst general tokens of sorrow and esteem.

April 15th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Royal Infirmary.

AT a meeting of the managers held this week Mr. John Walcot presented an interim report by the house committee on the state of the fire appliances in the infirmary. In the report it was recommended that the more urgent of the suggestions made by the firemaster should be at once carried out at an estimated cost of £83 and that the infirmary should be connected with the police office by a special telephonic wire. The report was approved.

Bequests by the Earl of Moray.

In allocating the sum of £50,000 bequeathed by the late Earl of Moray to the city of Edinburgh, county charities, and other institutions, his trustees have apportioned the sum of £20,000 to the University Court of the University of Edinburgh as an endowment for the promotion of original research in the University, £3500 to the Sick Children's Hospital, £2500 to the Leith Hospital, £2000 to the Longmore Hospital for Incurables, £1000 to the Chalmers' Hospital, £1000 to the Church of Scotland Deaconess's Hospital, £500 to the Victoria Hospital for Consumption, £500 to the Maternity Hospital, and £100 each to the New Town and Western Dispensaries, the Dental Hospital, and the House of Refuge.

Edinburgh University Graduation Ceremonial.

At the spring graduation ceremonial, which took place on the afternoon of Saturday, April 11th, Principal Sir William Muir, Vice-Chancellor of the University, being in the chair, one of the four gentlemen presented by Professor Sir Ludovic Grant for the honorary degree of LL.D. was Dr. Douglas Argyll Robertson. The address to graduates was delivered by Professor Prothero, who occupies the Chair of History in the University.

Opening of the Royal Observatory, Edinburgh.

The new Royal Observatory on Blackford Hill, Edinburgh, was formally opened on Tuesday, April 7th, for the teaching of astronomy on University lines. Lord Balfour of Burleigh, Secretary for Scotland, performed the ceremony of declaring the Observatory opened. Among those present were the principal and many of the professors of the University, as well as a large number of ladies and representatives of scientific societies throughout the country. The Astronomer-Royal for Scotland, Professor Copeland, read an interesting account of the history of the Observatory, and the architect, Mr. W. W. Robertson, gave an explanation of the reason of some of the architectural arrangements. The observatory is furnished to a large extent by the astronomical instruments and library presented to the nation a few years ago by Lord Crawford.

Deputy Commissionership in Lunacy.

Lord Balfour of Burleigh, Secretary for Scotland, has appointed Dr. Charles Macpherson, Bonar Bridge, to be a Deputy Commissioner in Lunacy for Scotland in place of the late Dr. Lawson. Dr. Macpherson is a graduate of the University of Glasgow and is medical officer to the Sutherlandshire Combination Poor-house.

The Case of Mr. Stocks.

The extraordinary treatment that has been experienced by Mr. G. M. Stocks will require, surely, some public explanation.

Glasgow Royal Infirmary.

Dr. J. W. Allan has been appointed dispensing physician to the Glasgow Royal Infirmary in place of Dr. Auld, resigned. Dr. Allan's promotion leaves a vacancy on the staff of the extra dispensary physicians.

Public Health Scotland Bill, 1896.

The corporation of Glasgow has drawn up a memorial on the subject of this Bill suggesting a number of additions and alterations. It is especially pointed out that many of the provisions of the Local Police Acts go further than those contained in the proposed Bill. The corporation are advised that the powers they thus possess would be interfered with in so far as these were in excess of those granted under the new Bill should it became law. Hence they suggest the insertion of a clause to prevent such interference. In particular it is instanced that the capacity of the authorities to deal with infectious diseases, school attendance and infectious diseases, supervision of dairies, &c., will be lessened unless such a clause is inserted in the Act. With regard to the section of the Act dealing with the inspection of dairies and which authorises such inspection by the medical officer only under an "order of the magistrate, justice, or sheriff," whilst examination of the cows is only to be undertaken if the medical officer is accompanied by "a veterinary inspector or some other properly qualified veterinary surgeon," the memorialists submit that these provisions are a most inopportune decline from the power of inspection already possessed by the Glasgow authorities by which the medical officer or sanitary inspector can at any time enter any byre or cow-shed if the milk obtained therein is being sent for sale within the city. The memorialists also object to the clause making the inspection of the cattle contingent upon the presence of a properly qualified veterinary surgeon. They insist that this is unnecessary as the detection of those conditions in cows which render the consumption of their milk dangerous can be made, and indeed was in the first place made, by medical men; they doubt too whether it would be possible in many counties to find a properly qualified veterinary surgeon to act with the medical officer.

The Health of Dr. T. B. Russell of Glasgow.

Dr. Russell's convalescence has not been quite so rapid as was anticipated, and he has applied to the Health Committee for a month's further leave of absence from his official duties.

The New Infirmary Scheme, Paisley.

The directors of the Paisley Infirmary are now in a position to proceed with the erection of the new infirmary according to the original plans. These plans involved the construction of three pavilions, but the estimates being much in excess of the amount anticipated it was decided to limit the building to two pavilions. The directors have, however, lately received information that the full amount—about £10,000—required for the third pavilion has been raised, and they have therefore decided to proceed with the original scheme. It is understood that the gentleman who has been mainly instrumental in obtaining the sum required is Mr. Peter Coats, himself a handsome subscriber to the scheme as well as the donor of the Nurses' Home.

University of St. Andrews and University College, Dundee.

The relations between the University of St. Andrews and the Dundee College do not improve, and the position appears to become more and more complicated. The Secretary for Scotland, who has been appealed to, feels himself precluded from interfering as long as litigation between the University and the College is going on. There is a party in the University Court determined apparently to keep Dundee outside the academic circle, and in pursuit of this policy an endeavour is to be made to equip St. Andrews with teaching in medical and scientific subjects. Thus, though the Universities' Commissioners have reported against the proposal, it was decided

Digitized by Google

at the last meeting of the University Court to establish lectureships in anatomy and materia medica at St. Andrews. The motion was carried by the casting vote of the chairman—the Marquis of Bute.

Montrose Asylum.

At the monthly meeting of the board the report of Dr. Sibbald, Commissioner in Lunacy, was read. It indicated complete satisfaction with the management and arrangements of the asylum.

April 14th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

"The Hospital for Incurables."

UNDER the above title a long series of letters have recently appeared in the daily journals of Dublin in reference to the action of the visiting committee of governors in dismissing two of the inmates for impertinence. The editor of the *Irish Times* is addressed by one who signs herself a "Lady Life Governor," and who complains bitterly of the injustice involved in such a severe punishment for such a comparatively small offence. She is subsequently attacked by one of the governors, a J.P. and town councillor, and accused of hysterical exaggeration, of misplaced sympathy, &c., and described in a rather sneering fashion as an example of the type of lady Poor-law guardian recently enfranchised in Ireland by Parliament. She and the other lady governors of this large and admirably managed institution have, however, found a champion. A moderate and sensible letter has appeared from Judge Kane stating that he, as one of the visiting committee, made a careful investigation into the case of the two women, both of whom had been insubordinate and impertinent to the lady superintendent, and therefore deserved punishment. The learned judge, however, goes on to say that the punishment which was inflicted was in his opinion "harsh, uncalled-for, and utterly disproportioned to the offence." He concludes by paying a high compliment to the lady governors for their special and invaluable services to the hospital. The whole occurrence will afford a lesson to a certain section of the governors of this great charity and perhaps serve to remind them that there are occasions when justice may be suitably tempered with mercy.

The Sale of Food and Drugs Act.

A curious case came before the Recorder of Belfast on April 8th. It was an appeal from the magistrates, who fined a man £3 and costs, or in default a month's imprisonment, in an action brought under Section 6 of the Sale of Food and Drugs Act, with reference to the sale of what is known as linseed cake meal. The meal had been sold to the inspector under the Food and Drugs Act, and when submitted to the public analyst he found it adulterated with 30 per cent. of farinaceous matter. For the defence it was urged that linseed meal and linseed cake meal were different substances, and that linseed meal practically could not be procured in an absolutely pure condition, and that linseed cake meal was not a drug within the meaning of the Food and Drugs Act. In giving his decision the Recorder said linseed meal appeared to be used for two purposes—feeding cattle and for human purposes. If for the former the 56th and 57th Victoria protected the purchaser, because it provided that an invoice should be given. This had not been done in the above case, and hence he must assume that it was not sold for cattle. If this was not done the seller had been guilty of an offence under the Act he mentioned (56th and 57th Victoria). It was used in medical practice, but it appeared that owing to its adulteration the faculty were giving up its use. That prosecution was to put an end to that. It had nothing to do with the selling of linseed cake for the purpose of cattle feeding nor had he (the Recorder) anything to do with that question. The prosecution was for selling linseed cake meal as such, and the opinion of one witness produced by the defendant was that it was not the article for which it was sold. Could anyone have a doubt when it was used for human purposes that it was a drug? He thought the magistrates had acted properly in convicting in that case, and he would confirm their decision, with costs.

Proposed Sewerage Scheme for Portadown.

The town commissioners of Portadown have for some time been anxious to abate a serious nuisance existing in a part of that town, and they adopted a scheme; but as it was proposed by it to empty the sewage into the River Bann, which is contrary to the Rivers' Pollution Act, the Local Government Board refused to advance the money (£1200) necessary to carry out the work. On April 8th, at a meeting of the commissioners, the matter was again very fully considered, when the town clerk read a letter from two civil engineers suggesting three possible solutions of the difficulty. After considerable discussion the board decided to defer its decision for a time, and appointed a sub-committee to confer with the engineers for the purpose of ascertaining whether any better arrangement could be adopted. Portadown is a very difficult place to arrange a sewerage scheme; for it is situated in a very flat district with the River Bann flowing through on its way to Lough Neagh. It is contrary to law to empty sewage into this river, and owing to there being no fall any other satisfactory plan is hard to devise.

The Winter Session, Belfast.

The winter session came to an end this week at both Queen's College and the hospitals. The medical examinations of the Royal University will begin on April 28th and the summer session at Belfast will commence at the beginning of May.

The Coroner and the Sanitary Authorities.

A matter which has never before arisen in Belfast came before the coroner's court on April 13th. It seems that the coroner considered it necessary to hold an inquiry in reference to the death of a child which had resulted from measles—a disease at present epidemic in some districts of Belfast. As the coroner did not want to subject the jury to the necessity of going into the house where the deceased child was lying and possibly carrying the disease to their children and families, and as he did not wish to put the police into the position of touching the body, as they also might convey the disease to their families, he requested the police to ask the sanitary authorities to have the body conveyed to the room specially fitted up in the new morgue for the purpose of depositing bodies of persons who died from infectious disease. The sanitary authorities replied that they had no power to do so, and accordingly the body was not removed. The jury not having seen the body of the child they could not hold an inquest. The coroner adjourned the inquest for a day and sent a formal application to the sanitary authority to have the body removed. The coroner said he was bound to send a report to the Lord Chancellor, and in case the sanitary authority did not carry out this order, and he exercised the same right as a magistrate, he would write to the Local Government Board. The section of the Public Health Act referred to by the coroner (the 158th) contains the following: "Where the body of one who has died of any infectious disease is retained in a room in which persons sleep or live, or any dead body is in such a state as to endanger the health of the inmates of the house or room is retained in such house or room, any justices may, on a certificate signed by a legally qualified medical practitioner, whose fee for giving the certificate shall be one guinea, to be paid by the sanitary authority, order the body to be removed at the cost of the sanitary authority to any mortuary provided by them, and request the same to be buried within a time to be limited in such order." At an adjourned inquest held on April 14th it was reported that the sanitary authorities had removed the body to the morgue. After hearing the evidence the coroner, in summing up, said that at the last meeting of the corporation the Lord Mayor had expressed his dissatisfaction at the high death-rate of the city—30 per 1000. He (the coroner) trusted some steps would be taken to try to reduce this rate. Unfortunately the sanitary authorities of Belfast had not adopted the Notification of Diseases Act, although most of the leading cities in the empire had. Measles was now prevailing in Belfast, and yet no steps had been taken to isolate such cases because the sanitary authority had no power to isolate them. The jury, in their verdict, said that the case clearly proved the necessity for the adoption of the Notification of Diseases Act by the corporation.

April 15th.

ROYAL INSTITUTION.—Dr. Poore is to deliver the Friday evening lecture on April 24th, at 9 P.M., on the Circulation of Organic Matter.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The English Language and the Mosoow Congress.

As was to be anticipated, the managers of the forthcoming International Medical Congress have given way on the language question. Communications may therefore be read in French, Russian, German, and English, the first-named remaining the only official language, whatever that may mean. The protests of Dr. Fränkel of Berlin and Dr. Felix Semon of London have likewise borne fruit, and a special section devoted to Laryngology will accordingly be instituted.

Death of Dr. Constantin Paul.

It is not long since the distinguished therapeutist Dr. Dujardin-Beaumetz was removed from our midst, and now another scarcely less renowned authority on therapeutics has joined the majority. Dr. Paul died on Sunday last from albuminuria at the comparatively early age of sixty-three. Appointed *agrégé* of the Paris Faculty in 1866, he became successively physician of the St. Antoine, Lariboisière, and Charité Hospitals, and was elected a Member of the Academy of Medicine in 1880. He took a special interest in diseases of the heart, and in 1883 he published a work that was widely read, entitled "Diagnostic et Traitement des Maladies du Cœur." But general therapeutics were his favourite study. In 1876 he helped to bring out a new edition of the once universally consulted "Traité de Thérapeutique et de Matière Médicale" of Trousseau and Pidoux. His communications on the action of drugs were numerous, no discussion on such a subject at the Academy of Medicine being considered complete without a pronouncement from him. This year he was elected president of the Société de Thérapeutique, and last year in the Fête Nationale (July 14th) the Cross of the Legion of Honour was publicly pinned on his breast in the courtyard of the Hôtel Dieu by the President of the Republic. Dr. Paul leaves one son, a well-known artist.

The Balsam of Peru Treatment of Scabies.

Dr. Jullien and Dr. Descouleurs call attention[1] to the advantages of the above non-sulphurous treatment of itch, their conclusions being based upon 300 cases observed both in private and hospital practice. It is known that the acarus placed on a watch-glass and exposed to sulphur fumes may remain alive for sixteen hours, and that it generally survives over an hour's immersion in flower of sulphur and Helmerich's ointment. Dr. Descouleurs placed six in contact with balsam of Peru and found that in ten minutes two were dead; in twenty minutes three more had succumbed; and the last of the six died soon after. This experiment confirms the conclusions of Burchardt, who, moreover, discovered that the balsam kills the eggs as well. It is probable that the volatile oil—cinnamein—that according to Frémy is the essential constituent of the balsam, kills the acarus at a distance through asphyxia and not through a corrosive action or by disruption, for Hebra has shown that the parasite can live for a week in water at 30° C., and Dr. Descouleurs has witnessed survival for three and a half hours in glycerine. The application of the method is simplicity itself. No soap is required, the balsam being painted on the surface and then gently rubbed into the whole body with the hand. The remedy being volatile penetrates readily into the "runs" without involving the necessity of opening these up. The patient remains thus all night, a warm bath being taken in the morning, when the cure is said to be complete. A repetition of the process, if necessary, produces no irritation of the skin. Inveterate cases that had resisted the classical and rather severe *frotte* at the St. Louis Hospital were all invariably cured by this method, which would seem to be specially indicated when scabies is complicated with impetigo, eczema, ecthyma, and boils, and also in cardiac cases, pregnant women, and feeble subjects with delicate teguments—e.g., babies. The rather agreeable odour of the balsam tells greatly in its favour, especially in private practice. Dr. Feulard stated that he has used it for some time in the form of ointment at the Children's Hospital, where he also successfully employs it against seborrhœic eczema of the scalp and impetigo.

April 14th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Health of Italy in 1895.

THE Commendatore Bodio, Director-General of Statistics for the Italian Kingdom, has drawn up a singularly clear and instructive memoir on the social condition of Italy in 1895. Beginning with the population, he tells us it increases steadily by an excess of births over deaths equal to 10 per annum for every 1000 inhabitants. The same proportion obtains in England (not in Scotland or in Ireland), in Germany taken as a whole, and in the Scandinavian countries, while in France the population still continues stationary, if, indeed, in some years the deaths have not actually exceeded the births. As to the sanitary condition of the kingdom, Signor Bodio contents himself with signalising the causes of death. Mortality from infective diseases (as, indeed, has been noted in THE LANCET) has for several years been on the wane. From small-pox 16,249 died in 1887, as compared with 2606 in 1894. Typhoid fever, which numbered 27,800 victims in 1887, counted no more than 13,639 in 1894. But, on the other hand, there has been a sensible increase in the deaths from bronchitis, pneumonia, enteritis, nephritis, &c., so that the total mortality is about the same as before. "This means," according to Signor Bodio, "that the poor population which fares badly, if even rudimentary precautions of hygiene are to-day a little less openly defied than before the sanitary service of the communes was enlarged and reorganised, is more severely decimated by the ordinary causes of death, which find their natural prey in organisms enfeebled and ill-provided with resisting power." The demonstration of the improvement attained is most evident in the city of Naples, where good potable water has replaced that of the wells sunk in the subsoil. Here Signor Bodio's figures are sufficiently eloquent. Typhoid fever, which numbered 468 victims in 1881, counted but 173 in 1893. The section on superior or professional education is full of interest. The excess of "avvocati" (barristers), a class which swells the ranks of professional politicians, not to say agitators, and is far too greatly represented in the Legislature, is still an evil to be deplored. The average per annum of "laureati in legge" (graduates in law) is, according to Signor Bodio, 1000, while those who can possibly make a livelihood out of it are about 500. Not only so, but the residual 500 of each previous year has to be counted in till the country literally swarms with "legal unemployed," who take refuge in journalism, platform propagandism, and every sort of political and social movement. Less to be lamented is the over-production of "laureati in medicina," for even if they do not practise they diffuse and raise the standard of that best of all knowledge—that which makes a man "the intelligent custodian of his own health." Still, the profession is greatly overstocked in Italy, with the inevitable result of a not always healthy competition. There are in the kingdom 66 practitioners for every 100,000 inhabitants, while in France the proportion is 40, in Austria 34, and in Prussia 32.

Professor Maragliano's Anti-Tuberculous Therapeutics.

The Ligurian Medical Congress has just been sitting at San Remo, and its most interesting feature has been Professor Maragliano's paper on Tubercolosi Latente e Tubercolosi Larvata (Tuberculosis Latent and Masked). He insisted on what Dr. Edward S. Smith pointed out some fifty years ago on the "pretubercular stage" and elaborately particularised the indications which precede what he described as the "explosion of tuberculosis." It is at this stage that sero-therapy has most chance of success, and therefore its diagnosis, from the point of view of his own therapeutics, is of primary importance. Carefully graduated injections of "tuberculina" he showed to have a special and valuable diagnostic power in determining the existence of the "stage" in question. He was followed by Professor Lucatello, who gave the results of 492 cases of tuberculosis treated on the Maragliano system by Italian practitioners. All these cases were well marked, most of them grave, but after the serum injections as many as 90 per cent. showed diminished pyrexia, arrest of pulmonary lesion, and increased weight of body. These results exceeded the expectations of Professor Maragliano himself. The two memoirs (Maragliano's

Digitized by Google

and Lucatello's) will shortly appear in the official "Atti" and cannot fail to interest the profession.

April 11th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Trional.

DR. DRESS has published in the *Medicinische Presse* an article on trional in which he claimed for this remedy advantages not possessed by other hypnotics. On account of its solubility it acts more quickly than sulphonal, and it produces a sleep which lasts from six to eight hours and is seldom followed by unpleasant symptoms. In one case a cumulative effect was observed, the explanation being the bad condition of the patient. Trional has no disadvantageous influence on the disintegration of albumin in the organism, thereby differing from chloral hydrate, which affects both the heart and bloodvessels. According to Dr. Dress the dose should not exceed 2 grammes (= 31 grains). Sleep of eight hours' duration may be obtained in all cases where wakefulness is due to pain, but in neurasthenic sleeplessness a dose of 1 gramme (= 15½ grains) is sufficient. Trional must not be taken dry, but always with about 100 c.c. (= 3½ fluid ounces) of warm liquid, and the patient may drink mineral waters in order to increase the alkalinity of his blood. Dr. Dress has employed trional in 30 cases, including 19 adults and 11 children. In the adults the sleeplessness was due in one case to neurasthenia, in 2 to hysteria, in 1 to phlegmon of the hand, in 3 to arthritis, in 3 to lumbago, in 1 to prurigo, in 1 to neuralgia of the fifth nerve, in 1 to the results of a burn, in 2 to intercostal neuralgia, in 1 to carcinoma of the womb, and in 3 to pulmonary phthisis. Among the children it was due to otitis in 3 cases, to meningitis in 1 case, to night-terrors in 2 cases, to chorea in 1 case, to enteritis in 2 cases, to pneumonia in 1 case, and to furuncle of the ear in 1 case. For the adults the dose varied from 1 gramme (= 15½ grains) to 1·5 grammes (= about 23 grains), and for children from 0·2 gramme (= about 3 grains) to 0·8 gramme (= 12 grains). In 28 cases sleep occurred after twenty minutes, but in 2 cases—those of phlegmon and enteritis—it came on only after three hours, and the patients complained of giddiness, tinnitus aurium, and nausea. In these instances the drug had not been taken in the manner directed.

"*Pseudo-hemisystolis.*"

At a meeting of the Medical Society of Prague Dr. Hering described the case of a female patient who had been admitted to the hospital with insufficiency and stenosis of the mitral valves and insufficiency of the tricuspid valves. The apex beat was in the sixth intercostal space, the radial pulse was frequent, irregular in rhythm and intensity, and very small. There was also pulsation of the jugular and subclavian veins and of both saphenous veins, the venous pulse alternating with the arterial. Dr. Hering has named this state "pseudo-hemisystolis." Though the occurrence of this condition has not hitherto been satisfactorily ascertained, it may nevertheless be supposed that under pathological circumstances the contraction of both ventricles does not take place at the same time. The temporary decrease of the volume of the pulse may be due to both the acceleration of the heart's action and to the trifling quantity of blood in the arteries, whereas the venous pulse is produced by the fact that owing to the insufficiency of the tricuspid valves a quantity of blood is driven back into the auricle during each systole of the right ventricle, and thus a wave is produced in the venous trunks.

Female Medical Practitioners.

The Minister for Public Instruction has just issued a decree relative to the recognition of diplomas obtained by women from foreign universities. In order to be admitted to practice in Austria the female candidate must be an Austrian citizen and must be at least twenty-four years of age. She must also have passed the full examination (Reifezeugnis) of an Austrian gymnasium and must have attended a five years' course in a medical school, the requirements of which are equal to those prevailing in Austrian universities. In every case the professors of the university to which the candidate will be admitted have to decide the question of her admission and the result is to be reported to the Ministry. If admitted the candidate is required to pass all the examinations with the exception of those in zoology, botany, and mineralogy.

Death of Professor Josef Spaeth.

Professor Spaeth, the celebrated Vienna obstetrician, died on March 29th in the seventy-third year of his age and about ten years after he had retired from academical life. He was born at Bozen, in the Tyrol, in 1823, was appointed assistant at the School of Midwifery in the Josef Academy in 1855, was promoted to the ordinary professorship in 1856, and in 1873 became chief of the obstetrical clinic, where he remained until 1886. From the long list of his scientific works I need quote only his "Clinical Gynæcology and Midwifery," "Outlines of Gynæcology," and "Text-book of Obstetrics for Midwives." In 1872 he was elected rector of the university. Professor Spaeth was not only an excellent teacher, but also a benevolent man, who practically exemplified his principles by bequeathing his entire fortune to the Society of Sick Students. The funeral was attended by a great many leading medical men, and his pupil, Professor Schanta, eulogised the merits of the deceased.

The Salaries of Medical Teachers.

According to a Bill which has just been submitted to Parliament the Government intends to augment the salaries of the professors. Hitherto there have been three scales—namely, £180 a year for the professors in Vienna, £166 for those in Prague, and £155 for those in other towns, the professor also receiving fees for his lectures. In Austria lectures are delivered five times a week and the fees are fixed at 10*s.* 6*d.* a half-year. Teachers have now the choice between the above salaries with the fees for lectures and the augmented salary, with gratuitous lectures, which has been fixed at £266, £300, and £333. "Extraordinary" teachers will be paid £133 and the *privat-docents* will be unpaid as hitherto.

April 12th.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The Moultan Murder and the Votiaks.

No medico-legal case of recent years in Russia has given rise to so much discussion and to so many and such diverse expressions of opinion as the trial and sentence of seven Votiaks for what is generally spoken of as the Moultan murder. Although the events which led to the trial occurred four years ago the matter is still as hotly discussed as though they had happened yesterday, in this respect resembling an equally notorious case at home. The intemperate expressions of opinion over the sentence on Mrs. Maybrick (a sentence passed nearly six years ago, and yet even now the subject of controversy in England and of interpellations in the American Senate) find their exact analogue in the articles and letters to the press which attempt to re-try the convicted Votiaks sentenced for the Moultan murder. The facts of that murder may be briefly stated. On May 6th (18th), 1892, the dead body of a Russian peasant was found in a marshy spot near the village of Moultan, in the government of Viatka (in European Russia). The head had been cut off from the body and was not found; several dorsal vertebræ had been removed so as to enlarge the opening into the thorax, and through this opening all the thoracic viscera had been extracted. There was some evidence to show that the victim had been suspended head downwards before life was extinct, in order to collect the blood flowing from an opening made into the abdominal veins. These circumstances led the authorities to conclude that the murder had been committed with a religious object, and that the blood and viscera had been thus obtained for the purposes of some rite of the nature of a sacrifice to heathen deities. Seven men, mostly but not all Votiaks, were tried and sentenced to varying terms of imprisonment. The case was tried a second time on appeal, but without affecting the result, and the convicted, or those which survive (for some are stated to have died since the trial), are now working out their sentence. The case is one of the highest medico-legal interest, but it would be impossible here to even mention the countless points which have led to discussion and to the formation of most opposite opinions even by experts. These points may be roughly classified as medico-legal and ethnological or anthropological. In the last number of the *Vratch* Professor Bellin sets out at

Digitized by Google

full length the medico-legal points, and comes to the conclusion that the necropsy was made so long (one month) after the murder that even the cause of death could not be ascertained, and his opinion is that the murder was an ordinary one and that the removal of the head and viscera was accomplished some days after death with the object of throwing suspicion on the Votiaks, who have frequently been charged with offering human sacrifices. The ethnological evidence on this last point is equally conflicting. M. Korolenko, a well-known writer, recently read a paper on this subject at a meeting of the Anthropological Society in the Academy of Medicine. He came to exactly the same conclusion, and further stated that no charge of human sacrifice had ever been substantiated against the Votiaks. On the other hand, a M. Poplavski, in an article in a lay paper, quotes several instances occurring in the last two decades where the evidence of human sacrifice was certainly very strong, if not conclusive, and mentions people now living who could corroborate his statements. Altogether the question is not unlike that of the charges of murder of Christian children brought against the Jews in the middle ages, and even now revived occasionally in some highly anti-Semitic corners of the Continent. Unfortunately no miraculous *alma redemptoris* broke from the dead lips of the murdered Russian peasant at Moultan to set at rest for ever the secret of his fate. It would be idle to speculate on the nature of that secret. In the presence of conflicting statements on both sides, and in the absence of the detailed evidence, which, however, twice satisfied the Russian courts of justice as to the guilt of the accused, it is impossible to form an unbiased opinion.

The Russian Ambulance Corps for Abyssinia.

The ambulance corps organised by the Russian Red Cross Society to proceed to Abyssinia in aid of the sick and wounded Abyssinians left St. Petersburg last week. A large crowd collected at the station and loudly cheered the expedition as the train started. Telegrams from Odessa announce the safe arrival there of the corps, and before these words appear in print it will be well on its way to Port Said, whither it is being conveyed on board the volunteer steamer *Rossia*. The expedition consists of ten medical men, six *feldschers*, twenty sisters of mercy, three agents, and one priest, and it is well supplied with provisions sufficient for three or four months. The Italians have consented to allow the expedition to pass through their African territory. Next week a similar but smaller corps is to be sent by the same society to Naples to aid in nursing the invalided Italians.

April 13th.

PHILADELPHIA.

(FROM OUR OWN CORRESPONDENT.)

The University of Pennsylvania.

THE medical faculty of the University of Pennsylvania recently submitted a recommendation to the board of trustees of the University to the effect that, beginning with the year 1896, the entrance requirements of the medical department be increased, and, further, that they should be increased annually thereafter until 1899, by which time they will have become the same as those required by the department of arts. It is also proposed to make the tuition fee $200 instead of $150 per annum. The Harvard Medical Faculty have recently adopted a rule, to become operative in June, 1901, making it necessary for candidates to the medical department to have a degree in arts, science, literature, philosophy, or medicine from a recognised college or scientific school. An effort is being made to establish a fellowship in anatomy in the University of Pennsylvania as a memorial to the late Dr. Joseph Leidy.

Jefferson Medical College.

Dr. George Dock of Ann Arbor, Mich., having declined the chair of Pathology and Bacteriology in the Jefferson Medical College, it was tendered to, and accepted by, Dr. W. M. L. Coplin, a former demonstrator in the institution, but recently Professor of Pathology in the Vanderbilt University, Tennessee.

"Emotion Products."

The Biblical expression, "Though your sins be as scarlet," would seem to have some foundation in fact if we believe the claims made by Dr. Gates, who says that the various human emotions and passions, good and bad, result in the formation of definite secretions. These, circulating in the blood, act upon the brain and thus cause vice or virtue. He believes that they are excreted with the perspiration, in which they can be shown by chemical tests. He says he had isolated forty "emotion products." Vice and virtue give rise respectively to poisonous or beneficial products, "but the worst of all these secretions is that of guilt." Dr. Gates states that if some of the perspiration of a person "suffering from conscious guilt" be mixed in a test tube with a few drops of selenic acid a pink colour will result.

The New Photography.

Interest in the "x" rays seems unabated, judging from the frequent reference made thereto by the daily papers and the periodicals. Several enterprising tradesmen of this city have the apparatus at work in their shop windows, and popular lectures on the subject are being given for the benefit of churches and other institutions. Some very excellent work has been done by Mr. Goodspeed and Dr. Cattell, however. Dr. Dalley and Dr. Egbert have been experimenting with a view to finding whether or not the "x" rays exist in sunlight. They used an ordinary photographer's printing frame, in which was fitted a sheet of aluminium $\frac{1}{17}$th of an inch in thickness. Under this was placed a positive plate or lantern slide, and next a sensitive unexposed plate. The frame was then backed with lead foil and tightly closed. It was then exposed to sunlight for two hours. A fair negative was obtained, although slightly over exposed. The positive plate was next replaced by a negative one and the time of exposure reduced to one hour. A better picture than the first was obtained, but it was found that the best results were yielded by an exposure of twelve minutes. Other experiments were made in which the aluminium was replaced by cardboard, vulcanite, and black paper, giving fairly good results in each case. These experiments would seem to indicate the need of care in the making of plate holders.

Obituary.

GEORGE F. STAINTHORPE, M.R.C.S. ENG., L.R.C.P. EDIN.

THE death of Mr. Stainthorpe of Newcastle at his residence, Benwell Old Lodge, at the age of seventy-four, will be much regretted by a large circle of friends, private and professional. This highly respected member of the medical profession was a Hexham man by birth, and obtained the diploma of the Royal College of Surgeons of England in 1854. He was chosen as a lecturer to the old Newcastle School of Medicine, and in 1859 became L.R.C.P. Edin. He commenced practice in the western part of Newcastle, and as that end of the town developed his practice became proportionally large and important. He was a kind and capable medical attendant, with whom many of his patients formed bonds of permanent attachment, while a certain reserve of manner was noticeable in him only when dealing with strangers. Some ten years ago he removed from the neighbourhood of the Cattle-market to Eldon-square, and two years later he decided to retire. He was attended during a lingering illness by Dr. Thomas Stainthorpe of Hexham, his brother, and Mr. Richard Ellis of Rye-hill.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The death of the following eminent medical man is announced:—Dr. L. Didelot, *Professeur Agrégé* of Physics in the Medical Faculty of Lyons.

LITERARY INTELLIGENCE.—A new and cheaper edition of "Home Nursing and How to Help in Cases of Accident," by Samuel Benton, L.R.C.P., M.R.C.S., &c., will be published next week by Messrs. Abbott, Jones and Co.—The Rebman Publishing Company, Limited, 11, Adam-street, Strand, have in the press for publication a serial work exemplifying the uses of the new photography in medical and surgical diagnosis, entitled "Archives of Clinical Skiagraphy," by Sydney Rowland.

THE

INTERCOLONIAL MEDICAL CONGRESS OF AUSTRALASIA, 1896.

FOURTH SESSION.

(FROM OUR SPECIAL CORRESPONDENT.)

THE fourth session of the Intercolonial Medical Congress of Australasia commenced at Dunedin, New Zealand, on Monday, Feb. 3rd, and closed on Monday, Feb. 10th.

Never in the history of medicine in New Zealand has so great a gathering of its followers taken place as that which the week following on Monday, Feb. 3rd, witnessed in Dunedin, the chief city of the South Island of the colony of New Zealand, and it speaks well for the spirit that animates our profession that men should flock from all parts of Australasia to interchange ideas, and to make the acquaintance of those whose names stand foremost in the ranks of medical science in those colonies.

The true keynote of the aims of these great medical congresses was struck by Dr. Batchelor, the President, in his opening address,[1] when he said that medical science is bound up closely with our own common humanity and that the people gladly acknowledge the benefits that it is daily conferring upon them. As showing the interest which the Government of New Zealand have taken in the Congress, it is worthy of note that that body has kindly promised to pay half the cost of publishing the transactions of the Congress.

It is impossible to estimate duly the labour entailed on the executive committee in the arrangements for the successful carrying out of the programme, which included also the social as well as the scientific objects of the meeting. The Congress met for the first time in New Zealand, so that we are not well experienced in Congresses, and the capacity of the authorities with regard to organisation was tested to the uttermost with a brilliant result. Dunedin may well be proud of the pleasant if arduous duty that she has had to perform, and it must be a great satisfaction to those who have devoted so much pains to secure the success of the Congress to know that it cannot but bear good fruit.

On the invitation of his Worship the Mayor of Dunedin (Mr. Wales) the members of the Congress partook of luncheon in the Choral Hall on the opening day, Monday, Feb. 3rd. The Mayor occupied the chair and was supported by his Excellency the Governor on his right and on his left by the President of the Congress, the Hon. Richard Seddon (Premier of New Zealand), the Hon. Mr. Grace, the Hon. the Colonial Treasurer, and many distinguished Dunedin citizens. In replying to the toast of the "Medical Profession" Dr. Batchelor heartily welcomed the visitors to Dunedin and emphasised the value of meetings of this nature.

One is vastly impressed with the value of these intercolonial congresses to all who thus gather together. Medical men are not as a rule apt to possess narrow conceptions of life and its duties, but even they are sometimes insular and parochial in their views and need occasionally to see other countries and rub shoulders with their professional brethren elsewhere. Our Australian *confrères* are to be congratulated on coming so far to assist us by their presence at the Congress. When they return home and tell their less fortunate stay-at-home brothers in Australia of the lovely scenery they witnessed in the lake district and the grandeur of the scene round about Mount Cook it will add to the misfortune of those who were not able to attend the Congress.

After the first morning the weather was glorious in the extreme. The air was keen and bracing, while the brightness of the sky and the clearness of the air which invested Dunedin during the Congress week was a marked contrast to the "heat wave" which drove so many away from Australia during this summer.

The whole business and pleasure of the gathering has been administered throughout with a cordial good fellowship truly representative of that spirit of hospitality which happily characterises all colonial peoples. The meeting took place in a city famed all over Australasia for its unbounded hospitality. Right well have the present citizens of Dunedin maintained their reputation in this respect, vieing as they did with one another in making social gathering after social gathering a series of huge successes.

GENERAL MEETING.

On Monday morning, Feb. 3rd, during a heavy downpour of rain, which gave way shortly after noon to truly lovely weather, the Fourth Intercolonial Medical Congress of Australasia began to assemble for the purpose of the enrolment of members in the Otago University Library. The members subsequently adjourned to the theatre associated with the University, where a general meeting of the Congress was held, about ninety members being present. The lecture-room presented an imposing sight as the members of the Congress rose to greet with acclamation the entry of Dr. Batchelor, the President, and Professor Scott and Dr. Barnett, the general secretaries.

The PRESIDENT thanked the members very kindly for the warm reception they had accorded to him. It was not his intention, he said, to make any lengthened remarks at that stage, but he felt it would be hardly gracious on his part to take the chair without attempting to express his heartfelt gratitude at the great honour which had been conferred upon him in his election to the important position of President. One felt grateful for honour of any kind, but those honours which came from his professional brethren were, he always thought, the very highest which could be conferred upon a professional man; and they had conferred on him the very highest honour the profession in Australasia could confer on one of their colleagues when they elected him to that important office. Certain deputies had been appointed by the various Governments. Mr. Springthorpe specially represented Victoria; Dr. Love, Victoria; Dr. Sprott, Tasmania; and Mr. James and Dr. Brown, New Zealand. There had also been a gentleman appointed by the Government of Western Australia, but his name had not yet been received.

Report of Executive Committee.

The report of the executive committee was then read and adopted. There were now on the roll of the congress more than three hundred members.

Dental Section.

The PRESIDENT mooted the desirability of adding a dental section to the congress and after some discussion it was decided "that the question of the establishment of a dental section be transmitted to the executive committee of the next congress with power to take action in the matter."

Contagious Disease Act.

Professor SCOTT (Dunedin) laid on the table a memorial from the Women's Christian Temperance Union of Victoria on the subject of the Contagious Diseases Act. After some discussion it was decided "that the memorial be referred to the public health section."

The Hon. Mr. GRACE (Wellington) placed on the table a number of important documents relating to the subject which had been forwarded to him from England—chiefly reports of parliamentary commissions and results of investigations.

An Intercolonial Medical Journal.

Dr. BARNETT (Dunedin) brought up the question of establishing an intercolonial medical journal. They had a small

[1] Published in THE LANCET, April 4th, 1896.

Digitized by Google

quarterly journal of their own and they knew also of the Australian Medical Gazette, the Australian Medical Journal, and the Intercolonial Medical Quarterly, but they were anxious to have one strong representative magazine for the whole of the colonies.

Mr. SYME (Melbourne) was also strongly of opinion that it was highly desirable that they should have in Australasia one strong united journal.

After considerable discussion it was decided by forty-two to twenty-six votes "that the Executive Committee of next session be invited to give special attention to this matter."

THE INAUGURAL CEREMONY.

The inaugural ceremony in connexion with the Congress was held in the Choral Hall in the evening and proved a brilliant success. Nearly all the members of Congress were present and a very large number of distinguished ladies and gentlemen from all parts of the colony; in fact, the hall was so packed that there was scarcely standing room left.

His Excellency the Governor, Lord GLASGOW, was received with great enthusiasm and declared the Congress open. In the course of his remarks he said: I believe that you are, nearly all of you, aware that this is one of a series of Congresses which have been held during the last few years in Australasia. The first was held in Adelaide in the year 1887, the second in Melbourne in 1889 (the year of the great exhibition there), the third was held in Sydney in the year 1892, and this is the fourth of the series. I may point out that Dunedin is a town of 40,000 inhabitants, whereas Melbourne is a town of nearly 500,000 inhabitants and Sydney of 450,000. On behalf of New Zealand I may perhaps be allowed to say that it gives us great pleasure to think that so many medical men have come over and have paid this visit to our lakes, because we feel sure that when they return to their country they will say there is no place where it is more delightful to spend a hot summer than in the lake country of New Zealand. I think the medical profession of Australasia are to be congratulated upon having formed this corporation, if I may use the expression, and of having undertaken to meet together in this series of congresses as they have been doing for the last few years. This nineteenth century is a century which is remarkable for many things: I think among other things it is remarkable for being a century of congresses. On every possible subject people meet together to talk it over, and there can be no possible doubt that in all scientific bodies it is of the utmost use that the members should meet together and talk over the subjects in which they are interested. We all know that this is the case with the Royal Society at home, and with the different associations connected with science, and we are to be congratulated on the fact that the great medical bodies in these colonies are not behindhand in taking an interest in their work, but have met in the same way as they do at home for the purpose of talking over the work in which they are engaged. I think it is hardly necessary for me to assure the members of the Medical Congress of the interest which the public of New Zealand take in their work. I do not think there are many medical men in the world who are fitted to do their work if they are not the friends of those among whom they practise. You are all centres of groups of friends, and it is through your friendship with them that you are able to do your work efficiently. It is because in this colony, as in the others, we are well acquainted with the usefulness of the work you are here to do and the way in which you do it that we heartily show our interest in the work you have assembled to do, and wish you Godspeed in it. I now beg, Mr. President, to declare this Congress, the Intercolonial Medical Congress of Australasia, open, and to wish it Godspeed in its work.

The Premier of New Zealand (the Hon. RICHARD SEDDON) then welcomed the visitors to New Zealand, and the President read the inaugural address on the Present and Prospective Conditions of Medical Education, which was published in THE LANCET of April 4th.

THE SECTIONS.

The work of the sections began on Tuesday, Feb. 4th.

MEDICINE.

PRESIDENT'S ADDRESS.

Mr. HAYWARD read the presidential address, prepared by Dr. A. A. Lendon of Melbourne who was unable to come to the Congress. The author of the paper invited attention to the question as to the share which the general practitioner takes in the advancement of medicine, as contrasted with the work effected by those who devote themselves to some special branch of their art. What has the general practitioner achieved in the past, and what might he be expected to accomplish in the future? It was a matter of general belief that most, if not all, the advances of medical science emanate from those who are working in the more populous centres, and in a great measure that belief was justified; but general practitioners were not, and ought not, to be merely middlemen engaged in retailing the benefits discovered by those who have greater opportunities for carrying on investigations in the ward or in the laboratory; that they have independent functions and ample opportunities for exercising them in everyday practice; and that they might—nay, ought—to assist in defining the principles and in improving the practice of medicine. The best answer to the first part of the question propounded immediately presented itself, the year 1896 being the centenary of a very great event—the introduction of vaccination by Edward Jenner. "Jenner was attracted to the study of this question by a tradition which was prevalent amongst the dairymaids. When he was an apprentice a young countrywoman's statement that she could not acquire small-pox as she had already had cow-pox riveted his attention. Jenner mentioned this notion to Hunter who publicly alluded to it in his lectures and encouraged his pupil to investigate its truth when he returned to the country. Jenner set to work and collected several cases of persons who, having had cow-pox by accidental inoculation, were found to be insusceptible of inoculation with small-pox virus. He next studied the disease of the cow and he came to the conclusion, since generally thought to be erroneous, that the cow-pox arose from a disease of the horse known as the 'grease,' and he further concluded that this disease had to be transmitted to human beings through the cow, otherwise it had not the protective virtue, for men who contracted sores on the fingers from attending to horses with greasy heels were easily inoculated with small-pox; these sores were therefore probably ordinary septic processes. Jenner ascertained further that milkers might have cow-pox more than once. The chief objection raised by those to whom Jenner first announced his opinion was that occasionally instances of small-pox occurred after accidental inoculation with cow-pox, so that the rule could not be absolute; moreover, those who had had small-pox were not exempt from taking cow-pox. Thus foiled Jenner set to work again and demonstrated that all the sores met with on the udder of the cow were not true cow-pox, and, further, that it was only in a certain stage of the development of the vesicle that the true virus of cow-pox could be communicated so as to be protective against small-pox. Milkers were liable to contract sores on their fingers which were not true cow-pox. In 1796 the climax was reached. A girl named Sarah Nelmes contracted cow-pox on her hand, and on May 14th Jenner inserted some of the matter taken from the vesicle into two superficial incisions on the arms of a boy named James Phipps. Six weeks later matter from a small-pox pustule was inserted into the boy's arms but he was found to be proof against inoculation." Had Jenner lived in the nineteenth century his services to humanity would perhaps have earned him rewards and titles. But it could scarcely be said that his discovery was not appreciated. The only danger to his reputation lies in the fact that this generation does not really know what small-pox meant a century ago and hence parents, moved by their infants' tears, were easily persuaded that "they did not hold with" vaccination and that it engendered all sorts of diseases in after life, as though skin eruptions and delicate health were unknown before the days of Jenner. Nothing had been added to Jenner's great discovery and nothing had been found to detract from it. The work Jenner did was essentially work of observation such as any general practitioner might carry out, and if its value were estimated by the saving of life it probably had higher merit than the enunciation of the antiseptic theory or the discovery of anæsthesia. What as to the future? What work was there for the general practitioner to do in the twentieth century to advance the science of medicine? The achievements of the past must be the augury for the future. The work that it was possible for him to do was boundless; it may not like Jenner's mean the saving of countless lives, but it will add to our common stock of knowledge. Could we suppose, for instance, that we had yet perfected the

Digitized by Google

methods of physical examination of the chest? Could we flatter ourselves that we were approaching the solution of the difficult problems of brain physiology and pathology? Could we assert that our methods of treatment of phthisis were strikingly successful? It would probably be, as of yore, in the class of chronic or of hereditary diseases, or of those ailments which do not require hospital treatment, that the general practitioner would find his richest harvest. One reason why the general practitioner is not doing so much to advance medicine in the present day, the address went on to say, was to be found in the voluminous literature—book and periodical, monograph and annual digest—with which he is supplied like so much peptonised mental food. "It prevents his thinking out problems for himself. He becomes too reverent for authorities and can scarcely believe the evidence of his senses if it conflict with what the books say. The authorities are not infallible and medical knowledge is transitional; the theory hazarded yesterday is accepted as truth to-day and may be disproved to-morrow. Let us question all authority—I do not say disregard it—as far as we are able and doubt all the more the statement that is most dogmatic. Then shall we, the general practitioners, having shaken off the trammels of tradition and authority, be more likely to do our share in the advancement of medicine as Jenner did his one hundred years ago."

Mr. Hayward (Adelaide) was subsequently elected chairman in this Section in the unavoidable absence of Dr. Lendon.

SURGERY.

PRESIDENT'S ADDRESS.

There was a general muster of members in the chemistry lecture room, the President, Dr. BATCHELOR, being in the chair, when

Mr. O'HARA, F.R.C.S.I., senior honorary surgeon of the Alfred Hospital, Melbourne, read his presidential address. He expressed regret that it should have been found necessary to divide medicine and surgery into separate sections. "The two sciences are so closely allied that I feel each section must be losing much valuable teaching in many subjects of common interest. There are in these days of over-specialism certain specialities which can stand alone, as, for example, that of the oculist; but the general surgeon must be a physician, and I hold that to gain eminence as a surgeon one must possess in a high degree the diagnostic powers which are so generally associated with the physician. Any address on contemporary surgery would be incomplete without reference to the loss sustained through the death of Pasteur. He undoubtedly first established the germ theory of putrefaction, and Sir Joseph Lister put it into practical use and introduced to the world the antiseptic treatment of wounds. Having had a large experience in operating under various atmospheric conditions, I have come to the conclusion that where sepsis occurs in a wound it has in most cases been introduced by the operator's hand or by the materials employed during the operation. The most prominent feature in the treatment of disease of late years has been the introduction of sero-therapy, and the most successful results up to date have been achieved with diphtheria. In 1890 Behring of Berlin published his discovery that the serum of immunised animals had a specific action on the diphtheria bacillus. To obtain a sufficient supply of the serum different animals were experimented on, and it was finally decided that the horse was most suitable. It was found to resist without suffering immense doses of the diphtheria poison, and a large supply of the serum could be obtained by simply tapping the jugular vein, a painless proceeding in the case of the horse. The published results of such authorities as Ehrlich, Kossel, Wassermann, Roux, Washbourn, Goodall, and Card in Europe are sufficiently satisfactory to induce us to use the serum in every case. It may not be a specific in all cases, but it has given the most remarkable results in the most hopeless cases and reduced the mortality to less than one-half of that recorded before its introduction. So absolutely hopeless is a case of inoperable cancer that any remedy suggested will be gladly welcomed and will not lack the benefits of a fair trial. That a malignant tumour has disappeared after an attack of erysipelas is an established fact. In my own practice I have had such an experience. The patient, aged fifty years, had a well-marked scirrhus of the right breast, with involvement of the axillary glands. I removed the breast and cleared out the axilla. In two years' time the patient consulted me for a small recurrence in the axillary scar, the greater portion of which I was able to remove. Some of the deeper parts were so intimately mixed up with the artery and vein that I had to leave them. Two days after operation she developed an attack of acute cellulitis, which extended down the arm to the hand. It was necessary to make free incisions into the arm and back of the hand and convalescence was slow. However, it is now six years since the last operation and she is in perfect health with no sign of recurrence. Fehleisen has had a similar experience with a case inoculated with pure cultures of the streptococcus erysipelatis. Bruns and Coley have seen improvements follow an attack of erysipelas and state that the results were more satisfactory in sarcoma than carcinoma. Coley also stated that the factitious erysipelas has not been attended with such good results as the accidental. In treating a case of inoperable recurrent carcinoma four years ago I was astonished to find that a strong solution of ichthyol seemed to arrest the growth. The patient's health improved, and the pain, which was constant and severe, gradually diminished. I determined to push the ichthyol and injected one drachm of a 10 per cent. solution into the margin of the growth daily. The improvement was most marked and when she left my care to return to England she had increased in weight, felt well, and the ulcerated surface had healed considerably at its edges and was only one-third the size it had been two months previously and all disagreeable odour had completely disappeared. I was not able to trace the patient subsequently and cannot, therefore, say what the ultimate result was. I have now under my care a woman whose breast I removed three and a half years ago for a scirrhus that had arrived at the stage of surface ulceration. The axilla appeared to be free at the time, and, her strength failing, I did not remove the glands, as is my custom. A year afterwards the glands became affected and there was marked œdema of the arm. I then cleared out the axilla and prescribed ichthyol internally. She gained flesh and improved rapidly in her general health. A small recurrence took place in the scar subsequently, which was removed, and in spite of all this operative interference she is now in better health than she was four years ago—now there is no sign of disease and she is still taking an ichthyol pill three times daily. I could quote many other cases of inoperable carcinoma where decided improvement took place after the administration of ichthyol, but I cannot claim to have absolutely cured one case, and I only bring it before you as a useful adjunct in the treatment of inoperable cancer. In sarcoma the results have been negative. If the parasitic theory of cancer expounded by Professor Foa at the Medical Congress in Rome proves to be correct we are then within reasonable distance of finding some remedy for it." After alluding to intestinal surgery Dr. O'Hara continued: "I take this opportunity to allude to the strictures passed by Sir W. Priestley on the tendency to over-operate in gynæcology. There is no doubt that along with the great improvements in the methods of operating in this specialty there has been a large increase in the number of operations performed. At the same time I think that, as the majority of gynæcologists are honourable men, outbursts of this kind can serve no useful purpose and only tend to bring unmerited opprobrium on the profession at large—a result which, I am sure, no one would regret more than Sir W. Priestley himself."

In this Section Mr. H. A. de Lautour led off with a paper on a Simple Apparatus for the Treatment of Dislocation of the Acromial End of the Clavicle.

In the Sub-section of Surgery devoted to diseases of the eye, ear, and throat Dr. JACKSON (of Melbourne) presided. A discussion took place on the Test for Vision in Sailors and Railway Men. A committee was appointed to draw up a report.

ANATOMY.

PRESIDENT'S ADDRESS.

Dr. WATSON, Professor of Anatomy in the University of Adelaide, delivered the following presidential address:—

"Allow me in the first place to return you my very cordial thanks for electing me president of this very important section. Any honour conferred by one's professional brethren I, in common with gentlemen occupying similar positions, appreciate very highly. It is not my intention at this late hour to occupy your time longer than is absolutely necessary. At this time of the year

Digitized by Google

the mind of the hard-worked professional man naturally turns to thoughts of rest and relaxation. I may add that the gathering together of so many professional brethren from all parts of Australasia in this hospitable and scientific focus of the most interesting country on the face of the globe must, apart from its scientific aims, tend to promote that social intercourse and brotherly love which should exist amongst the members of a learned profession such as ours. Our section, although low down on the list, includes those subjects upon which the basis of all scientific medicine must naturally rest. The whole fabric of clinical skill stands on a foundation of anatomy, physiology and pathology and pharmacology requiring for their comprehension a prior knowledge of the subsidiary sciences of physics, chemistry, and biology. The most profound knowledge of the above subjects as pure sciences does not by itself qualify a man for the conscientious practice of his profession. The teacher who only deals with anatomy as a pure science often fails to attach due value to those points which are important in the practice of medicine and surgery. Such a teacher attaches a high value to pure sciences as a means of cultivating the power of observation and stimulating and exercising the reflecting and reasoning faculties. We have heard the same thing said of dead languages, &c., so prone to create hopeless, helpless exasperation in otherwise intellectual individuals not possessing a congenital bias towards their study. It goes without saying that, without ample practical experience, pure scientists cannot be satisfactory healers of the sick. As well might one expect a man to erect fortifications and build bridges who, although he had gone through a course of mathematics and made himself familiar with trigonometry and the calculus, had not practised in the workshops. It cannot be denied that our profession has undertaken the charge and patronage of a body of knowledge only part of which has an application in practice. We do not study anatomy and physiology merely for the sake of pathology, or pathology merely for the sake of cure. For example, physiology of the brain has been studied with a large amount of success in order to explain the ordinary operations of our mind. In fact, it might be said that psychology and the studies depending upon it are at present waiting on physiological investigation; and physiology is a pure science apart entirely from its application in medicine. And the same is true in pathology, which is an indispensable handmaid to physiology. If we were to require our students to study only so much physiology and pathology as are required for the recognition of the diseases they will be called on to treat what would become of the studies of physiology and pathology themselves? The main thing in purely professional education is that the practitioner shall have a scientific interest in his work. This serves a double purpose, because, in addition to being the best guarantee for conscientious treatment, the interest in one's work becomes permanent because it is a scientific interest. This is too often overlooked. There is nothing we want so much as to have an abiding interest in our ordinary work, and it is only a scientific interest which can prevent it from becoming monotonous and stale. Everyone ought to know that the good medical man has not only to possess the requisite knowledge but to have an effective interest in his cases; and what interest can be so good for his patient as a scientific interest? The accompanying sympathetic interest is not acquired; it is cognate and instinctive rather than taught, and I hope we all have it without any training. What the medical man wants to know are the cause and the course of the disease. What does that mean but as intimate a knowledge as we can have of the normal and abnormal growth of tissues! A mere recognition of symptoms and a book of prescriptions added to a pleasant manner may make a student a financially successful practitioner, because unfortunately the general public cannot understand what more is required. But from an educational point of view a medical man who confines himself to that is simply a legalised quack. What he ought to know is cause, and effect, not signs and symptoms alone. The signs and symptoms are effects, and he ought to know their cause: only then is his occupation a profession, and not a mere money-making investment of his life; only then does the patient have the best that we can do for him, both in point of knowledge and of interest in his case. At present the medical profession in every civilised country has undertaken the patronage of anatomy and physiology, and their patronage consists in requiring our students to study them. All professions which can claim to be learned professions are patrons of a learning which is not merely useful for money-getting, but the value of which is as knowledge—mere knowledge; and what knowledge is of greater value than the knowledge of ourselves?"

[Our correspondent expresses his indebtedness to the *Otago Daily Times* for the reports of the presidential addresses in the various sections.]

(To be continued.)

Medical News.

UNIVERSITY OF EDINBURGH.—The following is the official list of candidates who have just completed the first professional examination for the degrees of M.B. and C.M.:—

Violet G. S. Adams, T. H. W. Alexander, Eliza M. Anderson, A. J. Baird, S. A. Ballantyne, J. W. Barrack, J. A. Black, G. H. Boyden, L. P. Brassey, George Brogden, Launcelot Bruce, Adam Brydon, Malcolm Campbell, Riley Carr, W. J. Collinson, John Craig, T. Ashton Davies, Horace B. Dodds, J. P. Douglas, D. R. Evans, Edward Ewart (with distinction), A. Binny Flett, A. S. Frank, William Girdwood, J. L. Green, Robert Hamilton, Herbert Harris, A. E. Henton, Katie W. Hogg, Edith J. FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. O. Hildebrand has been promoted to an Extraordinary Professorship of Surgery. Dr. Oestreich has been recognised as *privat-docent* in General and Anatomical Pathology.—*Greifswald:* Dr. Otto Schirmer has been promoted to the Chair of Ophthalmology in succession to the late Dr. Rud. Schirmer.—*Cracow:* Dr. Klecki has been recognised as *privat-docent* in General and Experimental Pathology.—*Halle:* Dr. R. Wollenberg has been promoted to an Extraordinary Professorship of Psychiatrics.

DIPHTHERIA MORTALITY IN LONDON IN 1895.—Diphtheria showed a smaller fatal prevalence in London last year than in 1894, though still in excess of the average for the decennial period 1885–94. There were 2316 deaths from this cause in the metropolis in 1895, but there were 3265 in 1893, and 2670 in 1894. Thus the decrease, substantial as it was in 1895 over the preceding year, compared still more favourably with the total of two years back. The rate of mortality from diphtheria in 1895, variously stated in the annual summary of the Registrar-General as 0·52 and 0·53 per 1000 persons living, contrasts with the decennial average rate of 0·38. The mortality in 1895 was by no means uniform over the several groups of sanitary districts, as we find that, taking 0·52 as the rate for London as a whole, the groups run thus:—Northern, 0·40; central, 0·42; western, 0·48; southern, 0·51; and eastern, 0·81. In London in 1895 the increase over the decennial average has been at the rate of 37 per cent., but in the northern group it has only been 8, and in the central group 17, the other groups showing—in the western, 33; in the southern, 42; and in the eastern group as much as 69 per cent. increase. Or reading the data in another fashion, we find that if London be regarded, in so far as the rate of mortality in 1895 is concerned, as represented by 100 then the various groups had mortality rates severally of 77 in the northern, 81 in the central, 92 in the western, 98 in the southern, and 156 in the eastern group. Both as regards increase over the decennial average and as regards relation to the total mortality ratio in 1895 the southern and eastern (especially the latter) show to great disadvantage. It is in reality the excessive rate in the eastern group which raises the London rate to its present position. The notified cases in the year 1895 numbered for the whole metropolis 11,426, and on this total the 2316 deaths work out to a case mortality of 20·3, but this total of notifications includes some duplicate notifications of single cases, though these are trivial in number as

Digitized by Google

compared with the aggregate of attacks. The hospital cases in London last year were 3688, or just 3 fewer than in the preceding year; but the number of fatal cases among them was much less—namely, 824, or 22·3 per cent. of the admissions, as compared with 1041 deaths, or 28·2 per cent. of the admissions in 1894. Whether the decline be put down to the use of serum or be explained in some other way it is a pleasing feature in the hospital records. In actual figures the decrease in deaths from diphtheria in London in 1895, as compared with the previous year, was 611; whilst if croup be added to the diphtheria deaths the total of fatalities reached 2460—a number only 376 fewer than in 1894, and 299 in excess of the decennial average.

WE are informed that the Peninsular and Oriental Company have recently entered into contracts for four mail steamers of the highest class, similar in type to, but larger than, the *Caledonia*, *Australia*, and *Himalaya*, now running in the Eastern services, which will accommodate about 500 first and second-class saloon passengers. These vessels are each 500 feet in length, with proportionate beam and power, measuring about 8000 tons register, with machinery to indicate 11,000 horse-power. They are being built by Messrs. Harland and Wolff and Messrs. Caird and Co., and the first two ships, which have been named the *India* (which was launched on Wednesday last) and the *China* (to be launched on June 13th), will be ready for service during the coming autumn.

BRISTOL HOSPITAL FOR CHILDREN AND WOMEN.—The thirtieth annual meeting of the subscribers of the Bristol Hospital for Children and Women was held on March 21st, the Mayor presiding. From the report it appeared that during 1895 there had been 855 children and 31 women admitted as in-patients, and 1237 women and 3096 children were treated as out-patients. The committee regretted that in consequence of ill-health Dr. Roué had been obliged to resign his appointment as one of the acting staff. The ordinary revenue of the hospital has not been sufficient to meet the expenditure by £150, so that, including the small balance to the debit with which the year commenced, the treasurer's account shows an adverse balance of £189 16*s.* 8*d.*

THE DIFFUSION OF SMALL-POX.—In Gloucester the intensity of the disease has been maintained, the record total of 210 cases in the week ending April 4th giving way to the total in the week ending last Saturday. But the daily notifications reached their maximum on Friday of last week, when there were 48 attacks brought to the knowledge of the Town Council. Next day the cases fell to 26, on the Sunday they fell further to 14, and on Monday of the current week only 13 fresh attacks were chronicled. It is to be hoped that this favourable decline may be continued, while the immense number of recent vaccinations will exert a beneficial effect on the progress of the epidemic. The rush to the public vaccination stations has not abated, the vaccination of some half of the citizens has been effected. The remaining half are not all unprotected, as a large proportion of the adult population have the benefit of infantile vaccination. In the fortnight ended on Saturday last there were no fewer than 4414 persons vaccinated by the public vaccinators, and the guardians have made a complete change of front, and have by their latest procedures hit the anti-vaccination party very hard indeed. There were 5 cases of small-pox in the Cheltenham Hospital at the close of the first week of April. At Bristol 11 cases of small-pox came to the knowledge of the health officer in the two weeks ended April 9th, 6 being connected with a previous case at Barton Regis. Two were so slight as to be difficult of diagnosis, and it took thirteen hours' search to find one patient in the city, this instance being illustrative of the dangers attending mild and unrecognised attacks. At Exeter ten days ago there were 13 cases in hospital, coming from St. Thomas, Heavitree, and elsewhere; and a resolution of the guardians to enforce the Vaccination Acts, which have for so many years been a dead letter there, was recently carried by a majority of 12 votes to 4. At Coventry the determination of the guardians to enforce vaccination has led the anti-vaccinationists to a resolve to stay if possible the carrying out of the guardians' intention. Cases of small-pox are reported at many places in the Forest of Dean—namely, 2 at Alvington, 4 at Steam Mills, 2 at Bollow, 2 at Whitcroft in Weston, and 1 each at Dinny and Cinderford Meend. The Westbury guardians, presumably acting as rural district council, have appointed an additional inspector and have contracted for an iron hospital. Three cases of small-pox have been brought into Swansea docks by the sailing vessel *Harland*, and all were conveyed to hospital. At Heywood the small-pox patients are progressing, but it is estimated that there are 1000 unvaccinated children in the town. At West Hartlepool one of the crew of the *Harland* has sickened of small-pox, as has also a young lady recently from Gloucester. There are many manifestations of the spread of small-pox by tramps in the vicinity of Gloucester and gradual widening of this influence is to be expected.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of this society was held on April 8th at 11, Chandos-street, W., Mr. Christopher Heath, vice-president, being in the chair. The deaths of two widows were reported, one having been in receipt of grants since May, 1860, and having received £1798, her husband subscribing thirty-six guineas. Fresh applications for grants were read from four widows and four orphans, and a sum of £80 10*s.* was given among them. Applications for further assistance were made from forty-eight widows and seven orphans, and a sum of £1141 10*s.* was recommended to be distributed at the July court. Four members were elected and the deaths of four announced. A further sum of £215 had been received from the executors of Miss Carpue, making in all £3215 paid. The following gentlemen were nominated for election as directors at the annual general meeting, to fill the vacancies caused by the death of Mr. Rouse and the retirement of the six seniors—viz., Mr. W. H. Bennett, Dr. Wilks, Dr. Frederick Roberts, Dr. Sylvester, Mr. Malcolm Morris, Mr. Fountaine, and Mr. Butlin. The annual general meeting was fixed to be held on May 20th, at 5 P.M.

THE LOCAL GOVERNMENT BOARD AND WORKHOUSE NURSES.—On Wednesday last Mr. Chaplin received a deputation at the House of Commons from the Workhouse Infirmary Nursing Association to discuss the question of the inadequate number of nurses employed in workhouse infirmaries, and necessary alterations in their status. The deputation was introduced by Lord Montagu of Beaulieu, who stated that the association was founded in 1879 in order to supply boards of guardians with competent and duly-trained nurses. Over 700 nurses had been appointed, and of these 135 were now at work. The present state of nursing in the majority of workhouse infirmaries was capable of improvement; it was desirable to promote the employment of paid and efficiently trained nurses in all such places; and the appointment of a hospital-trained lady superintendent to be at the head of each staff of trained nurses was essential to the efficiency of the system. The President of the Local Government Board said he would carefully consider the complaint that in so many infirmaries the nursing staff was still insufficient. The question of want of accommodation was a difficult one. As to pauper assistants, the Local Government Board had again and again discouraged their employment.

PRESENTATIONS TO MEDICAL MEN.—Mr. J. Lacy Firth was presented, at the Bristol General Hospital on the 19th ult., by the resident medical officers, students, and nursing staff, with a handsome writing table as a mark of their esteem upon his retirement from the post of resident medical officer, he having been appointed assistant surgeon to that institution.—Dr. J. S. Riddell, lecturer to the Police and Railway Ambulance Class, Aberdeen, in connexion with the St. John Ambulance Association, has been presented by the members of the class with a handsomely mounted microscope.—Mr. James Cantlie, who has been in practice for the past nine years at Hong Kong, has left on account of ill-health to return to England. Prior to his departure from that city he was presented with several addresses from public bodies, signed by representative members of the community, and was also the recipient of a handsome tea and coffee service.—On the 8th inst., Dr. W. B. Mackay of Berwick-on-Tweed, on the occasion of presenting the certificates awarded to the ambulance classes under the auspices of the St. John Ambulance Association to the members of the North-Eastern Railway servants, was the recipient of three volumes of medical works.—Dr. J. Johnston of Bolton, has been presented by the members of the ambulance class connected with the Mawdsley-street Evening Continuation

Digitized by Google

School with a handsome ebony silver-mounted walking-stick and a pocket-book.—Dr. J. Hilton Thompson of Bolton, at a meeting in the St. Luke's School, on Saturday last, to present the certificates and medallions to the successful members of the ambulance class, was the recipient of a handsome breakfast service and a set of jugs.

FOOTBALL CASUALTY.—On the 14th inst, at Nelson, in a Lancashire League match between the Nelson and Southport Central teams, the Nelson's outside left forward fractured his right leg below the knee.

A GENEROUS GIFT.—Some time ago the directors of the Paisley Infirmary issued an appeal for subscriptions. Mr. Peter Coats, of the Ferguslie Thread Works, has promised a donation of £10,000. Mr. Coats previously subscribed £5000, and is stated to be also building a nurses' home at a cost of about £10,000.

FRENCH HOSPITAL AND DISPENSARY. — The twenty-eighth anniversary banquet on behalf of the funds of this institution is announced to take place at the Whitehall Rooms of the Hôtel Métropole on Saturday, April 25th, his Excellency the French Ambassador (Baron de Courcel) in the chair, supported by the Lord Mayor of London. Tickets (£1 1s.) may be obtained from the hon. secretary, French Hospital, Shaftesbury-avenue, W.C.

Parliamentary Intelligence.

CURRENT NOTES.

Venereal Disease in the Army.

MR. JAMES STUART has given notice that he will endeavour to find an opportunity to call attention to the state of the army in India and elsewhere as regards venereal disease and to move a resolution on the subject. In the present state of Parliamentary business there is little prospect of Mr. Stuart finding the opportunity he desires.

Shops (Early Closing) Bill.

Several Members not satisfied with the consideration given to this Bill by the Grand Committee on Trade have notified that it is their intention to move that the measure be now dealt with in Committee of the whole House.

Nursing in Workhouse Infirmaries.

On the afternoon of Wednesday, April 15th, in his room at the House of Commons, Mr. Chaplin, President of the Local Government Board, received a deputation from the Workhouse Infirmary Nursing Association. The object of the deputation was to ask the right hon. gentleman to take steps to secure the appointment of only trained nurses to workhouse infirmaries, to define the position of the trained nurse in relation to the untrained matron and the master of the workhouse, and to abolish pauper help in nursing duties. Lord Montagu, in introducing the deputation, explained to Mr. Chaplin that the Association was founded in 1879 in order to supply boards of guardians with competent and thoroughly trained nurses; that during the sixteen years over 900 applications have been received from boards of guardians, and over 900 nurses have been appointed; 135 of these being now at work. Mr. Frederick Feeney, a guardian of the poor of Cheltenham, addressed Mr. Chaplin with special reference to the unsatisfactory state of the nursing arrangements in rural districts. Miss L. Twining dwelt on the importance of separating infirmaries from workhouses, and Dr. Dolan of St. Luke's Hospital, Halifax, expressed the views of the association with regard to the position of the trained nurse.—Mr. Chaplin in his reply spoke in complimentary terms of the work of the association, and recommended it to the support of the public. He assured the deputation that the Local Government Board were fully alive to the defects in the present system of nursing in these institutions. They had already done something to remedy them although he confessed that much remains to be done, and he promised to give most careful attention to the views put forward by the deputation.

The London Water Question.

At this sitting there was a short debate upon the supply of water in the East-end of London. It arose in connexion with a Bill whose main purpose was to increase the statutory pressure required of the East London Water Company; but in view of certain circumstances connected with the promotion of the measure, the second reading was not pressed, and in the end the Bill was withdrawn.

Grants to University Colleges.

Mr. Balfour, replying to a question by Mr. Carvell Williams as to whether the Parliamentary grant to King's College would not only be restored but considerably increased, said that no increase was proposed in the Estimates this session. The Chancellor of the Exchequer, in accordance with an undertaking given by him to a deputation which waited upon him, had appointed three gentlemen—Mr. T. H. Warren, President of Magdalen College, Oxford; Professor D. G. Liveing, Fellow of St. John's College, Cambridge; and Mr. Chalmers of the Treasury—to visit the Colleges sharing in the grant made to Universities and Colleges in Great Britain and to investigate the character and quality of the University work done and to inquire generally into the position which such College occupied both financially and in other respects. When their report was received, which the Chancellor of the Exchequer expected would be some time in the autumn, he would be in a position to judge whether a case had been made out for recommending Parliament to increase the sum to each of the Colleges sharing in the grant.

HOUSE OF COMMONS.

THURSDAY, APRIL 9TH.

University of London.

Sir Albert Rollit questioned the Government again with regard to their intentions in the matter of the report of the Gresham Commission, but Sir John Gorst could give no further information than to say that the subject is still under consideration.

FRIDAY, APRIL 10TH.

The Ventilation of the House.

When the House was in Committee of Supply and considering a vote of £23,900 for work on the buildings of the Houses of Parliament Dr. Farquharson raised the question of the ventilation of the House of Commons, and asked the Government for information as to what had been done. Mr. Akers-Douglas, First Commissioner of Works, in his reply said that while better ventilation might be required in other portions of the building, so far as the legislative chamber was concerned it was certainly one of the best-ventilated rooms that could be found anywhere. He could bear witness to the very great care which was taken by the officials in charge of the ventilating department. He had taken a personal interest in the matter since his appointment as First Commissioner, and had made a point of constantly visiting the ventilating rooms, and hon. Members who had accompanied him had been greatly struck with the enormous staff and the appliances which were provided in order to secure the comfort of Members of the House. He had, in accordance with a promise made when the Estimates were under discussion last year, gone carefully into the subject, and he thought he had met the different complaints and remedied the various grievances which were then urged. Ventilating shafts had been placed in the Victoria Tower and improvements had been carried out in the kitchen and smoking rooms and other parts of the building.

Portsmouth Quarantine Stations.

Two sessions ago exception was taken to the money annually spent on the maintenance of the two quarantine stations near Portsmouth for the treatment of plague and yellow fever, and this session the Government brought in a Bill to abolish the charge and hand over the stations to the port sanitary authorities for the purposes of the latter. The Bill was brought up at this sitting of the House, and after being explained by Mr. T. W. Russell was read a second time.

MONDAY, APRIL 13TH.

Inquests on Railway Accidents.

Mr. Channing asked the President of the Board of Trade whether he could state what was the number of inquests held on railway servants killed in the discharge of their duties during the year 1895; at how many of such inquests the Board of Trade was represented by an inspecting officer, a sub-inspector, or other representative; and in how many instances the coroner applied for an official of the Board of Trade to attend as an assessor, in pursuance of Section 8 of the Regulation of Railways Act of 1871.—Mr. Ritchie replied: Two hundred and seventy-six coroners' returns were received by the Board of Trade in 1895. In no case did the coroner apply for an assessor in pursuance of the Act, but in three cases coroners asked for technical assistance, and in two cases such assistance was given, in one by an inspecting officer and in the other by a sub-inspector. In the third case the coroner asked for scientific evidence, and this the Board of Trade were unable to give.

Lead Poisoning.

Mr. John Wilson (Falkirk) asked the Secretary of State for the Home Department if he would order an inquiry into the conditions of the enamel industry with a view to dispense with the use of lead, so that the large percentage of deaths through lead poisoning might be averted.—Sir Matthew White Ridley said in reply: The hon. Member will no doubt remember that the various lead industries formed the subject of an exhaustive inquiry by a departmental committee three years ago, as a result of which stringent special rules have been established for factories where lead is used in plate enamelling. Considerable difficulty, however, is experienced in getting the workpeople to obey the rules, nor am I satisfied that they might not be amended. I propose, therefore, to have a further inquiry made.

Ill-treatment of Children.

Mr. MacAleese asked the Secretary of State for the Home Department whether he had seen the report of the National Society for the Prevention of Cruelty to Children, wherein it was stated that there were investigated last month 1965 complaints of neglect, starvation, ill-treatment, and other wrongs upon children, that 1837 of those complaints were found to be true, and affected the welfare of a large number of children of various ages, and that eighteen of the children so affected died; and would the Government consider the propriety of making more stringent the laws in existence for the protection of helpless children?—Sir Matthew White Ridley replied that his attention had not been previously called to the report referred to. The Prevention of Cruelty to Children Act of 1894, which consolidated and extended previous legislation on the subject, was passed after much discussion in Parliament, and he had not as yet seen any reason to suppose that it was ineffective for its purpose. No representations to

Digitized by Google

the effect that the law required strengthening had been made to the Home Office by magistrates or others concerned in its administration, but should any such representations be received they would, of course, be carefully considered by him.

TUESDAY, APRIL 14TH.

The Small pox Epidemic at Gloucester.

Mr. Ascroft asked the Secretary to the Treasury, as representing the Postmaster-General, if any means were being taken by the postal authorities at Gloucester to disinfect the letters and papers deposited in the pillar boxes which were situated in the infected areas; and whether he would cause inquiries to be made as to the same and give such instructions as he may be advised were necessary to prevent the spreading of the small-pox epidemic to other parts of the kingdom?—Mr. Hanbury replied: Instructions have been given for the use of disinfectants at the Gloucester Post-office with the view of reducing as far as practicable the risks of infection during the prevailing epidemic.

BIRTHS.

ATKIN.—On April 10th, at Fern Bank, Sheffield, the wife of Charles Atkin, F.R.C.S. Eng., of a son.

BERNAU.—On April 6th, at Napier, New Zealand, the wife of Henry F. Bernau, M.R.C.S., L.R.C.P., of a son.

BOXALL.—On April 12th, at Rudgwick, Sussex, the wife of Frank Boxall, M.R.C.S., L.R.C.P., of a son.

COOK.—On April 14th, at Stewarton, Ayrshire, the wife (née Puckle) of James Cook, M.B., C.M. Glasg., of a son.

EDWARDS.—On April 12th, at Brunswick-square, W.C., the wife of Robert Edwards, M.D., of a son.

FOLKER.—On April 7th, at Havelock-place, Hanley, Staffordshire, the wife of Herbert H. Folker, M.R.C.S., L.R.C.P., of a daughter.

GAGE-BROWN.—On April 9th, at Cadogan-place, the wife of C. H. Gage-Brown, M.D. Edin., of a daughter.

KING.—On April 14th, at Nicholas-street, Chester, the wife of Henry W. King, M.D. Edin., M.R.C.S., of a son.

LIEBSTEIN.—On April 9th, at Cairn Ryan, Preston, Brighton, the wife of David W. Liebstein, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

MITCHELL.—On April 10th, at Cumberland-terrace, Regent's-park, the wife of Surgeon-Captain H. Mitchell, 2nd Life Guards, of a son.

SIMMONS.—On March 22nd, at Standerton, Transvaal, the wife of Herbert Charles Simmons, M.R.C.S., L.R.C.P., of a daughter.

THOMSON.—On April 9th, at Bridge House, Retford, the wife of George Thomson, M.B. Edin., of a daughter.

MARRIAGES

ALLEN—FRY.—On April 9th, at the Parish Church, Berwick-on-Tweed, William Herbert Allen, M.B. Cantab., second son of Theophilus Allen, of Stanyards, Chobham, to Elizabeth Christine Fry, elder daughter of George Fry, of Carlin Brae, Berwick-on-Tweed.

AVERILL—WRIGHT.—On April 9th, at Park-green Congregational Church, Charles Averill, M.D. Durh., Macclesfield, to Helen, youngest daughter of the late Joseph Wright, Summer hill, Macclesfield.

BOKENHAM—MAYO.—On April 8th, at the Parish Church, Cheshunt, Thomas Jessop Bokenham, M.R.C.S., L.R.C.P., of Devonshire-street, Portland-place, W., to Edith, eldest daughter of the late Charles W. Mayo of Colesgrove, Cheshunt, Herts.

BULLOCK-GRIFFITHS.—On April 9th, at the Parish Church, Ellesmere, Charles Penry Bullock, M.A. Oxon., M.R.C.S., L.R.C.P. Lond., of Oswestry, to Francis Elizabeth (Bessie), younger daughter of Mrs. Griffiths, Ivy House, Ellesmere.

CROWDY—SAUNDERS.—On April 8th, at St. Mary's, Bryanston-square, W., Francis Demainbray Crowdy, M.A., M.D. Oxon., of Belvedere House, Torquay, to Florence May, daughter of the late J. B. Saunders, Esq., of The Knoll, Torquay.

DOUGLAS—PEAKE.—On April 9th, at All Saints', Norwood, John J. Douglas, M.B., F.R.C.P.E., son of David Douglas, Publisher, Edinburgh, to Margaret Emmeline, younger daughter of Charles B. Peake, Woodend, Norwood.

EADY—BOYLE.—On April 11th, at Christ Church, Chelsea, George John Eady, M.D. Brux., of The Elms, Enfield, to Luna, daughter of the late Joseph Boyle, of Clapham-common.

JAMESON—STURDY.—On April 23th, at the Church of St. Mary Magdalen, St Leonards-on Sea, James Elliot Jameson, B.A., M.B. Dubl., of Upwell, Cambridgeshire, to Elizabeth Margaret (Madge), youngest daughter of Mr. Sturdy, of Warrior-gardens, St. Leonards.

REID—MAWER.—On April 11th, at Unity Hall, Wood Green, Arthur Lestock Reid, M.R.C.S., L.R.C.P., to Leila Ada, the eldest daughter of W. Mawer, F.G.S., of Southgate, Middlesex.

SMITH—BINDLOSS.—On April 8th, at Christ Church, Brondesbury, J. Anderson Smith, M.D. Lond., eldest son of J. R. Smith, Esq., of Hull, to Amy Helen Maud, younger daughter of the late Rev. Edward Bindloss, of Archangel.

UPHAM—NORBURY.—On April 9th, at St. George's Church, Stonehouse, Plymouth, Surgeon Charles Hazlitt Upham, R.N., son of the late Charles H. Upham, Esq., of H.M. Civil Service, to Mina Ethel Olive, eldest daughter of Inspector-General H. F. Norbury, C.B., M.D., R.N., of the Royal Naval Hospital, Plymouth.

DEATHS.

FRIDAY (24th).—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Dr. Dundas Grant: The Modern Methods of Operating on the Tympanic Attic and Mastoid Process.

ROYAL INSTITUTION.—9 P.M. Professor G. V. Poore: The Circulation of Organic Matter.

SATURDAY (25th).—ROYAL INSTITUTION.—3 P.M. Professor W. B. Richmond: The Vault of the Sixtine Chapel.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the second half-yearly volume for 1895 was given in the issue of Dec. 28th. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1895 are now ready. Bound in cloth, gilt lettered, price 18*s*.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*.; by post, 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

MEDICAL SECRETS AND THE TRAINED NURSE.

A WRITER in *The Times* gives a facetious turn to the discussion of the interesting question of medical privilege, which in its grave aspects must be considered for the present as *sub judice*. Nothing is more satisfactory in the discussion than the general recognition of the reticence of the great profession which gets deeper insight into human nature than any other. The letter we refer to must not be taken too literally, but in its way it is a striking illustration of this point, and suggests the sad consequences of extending to nurses the severe silence which is imposed on medical men. The writer must be of the female sex from the feeling way in which she expresses the dread and the dulness with which she anticipates such an extension of ethics. The freer tongue of the "trained nurse" gives animation to the sick room, which even extends to the whole village or neighbourhood of her operations, "till some busybody in high life awakens to the fact that she is the bee that carries the pollen of unrighteous gossip from door to door." The writer surely does not mean to imply that "training" *per se* adds to the vice of lingual incontinence. The old nurse in that respect at least might fairly be matched with the modern. But we may make this admission: that if a few of the lessons in transcendental therapeutics &c. were exchanged in the training of our modern nurses for a few lessons in common sense and the management of patients and of their friends great advantage would accrue all round. And amongst the earliest of such lessons would be the reverence due to the privacy of human nature in its weakest forms and states.

S. C. R. M.—Our correspondent's suggestive remarks will receive our attention. Nothing would be gained by the publication of his letter.

Doubtful has omitted to enclose with his communication his name and full address.

"THE POISON OF THE PRIMULA."

To the Editors of THE LANCET.

SIRS,—The following case, at present under my care, will no doubt be interesting as bearing upon your paragraph on the primula obconica in THE LANCET of March 28th.

On Feb. 28th last I was consulted by two nuns, one of whom complained of itching on the wrists, hands, and cheeks, and also of chronic dyspepsia. I gave an ointment and a stomach mixture containing bichromate of potash, thinking that the skin troubles were dependent on the stomach affection. On March 9th the nuns returned with the same symptoms, there being nothing to see except diffuse redness of the hands. On March 14th they came again, saying the itching got worse. Being summoned on the 17th I was surprised to find the back of the hands, especially the left one, the wrists, and cheeks intensely swollen, and the right eyelids œdematous, along with intolerable itching, which effectually warded off sleep and rest. The parts were of a dusky hue and the temperature registered 103° F. I was doubtful as to its being true erysipelas on account of the hue and so I enquired carefully as to where she had been and what she did. I was told that it was her duty to attend to the plants in the glass-houses of the convent. This called up in my mind what I had read in the "Medical Annual" about a year ago concerning a dermatitis occurring in gardeners from handling primulas, and I at once concluded that this was just such another case, especially after being assured that they had a great number of these plants. I painted the affected parts with ichthyol, which soon stopped the itching, and in about a week every trace had disappeared (during which time she kept her bed); but last Monday she came to me complaining of itching on the back of the left fingers, where I found several vesicles. The paint was reapplied and with the same excellent results.

I am, Sirs, yours truly,

Victoria-villas, York, March 31st, 1896. P. W. SCHMIDT, M.B. Edin.

To the Editors of THE LANCET.

SIRS,—Last autumn a man came to my surgery suffering from a severe inflammatory eczema extending from the fingers to the elbows; both sides of the cheeks and neck were in the same condition. On questioning him I found that he was a gardener and had worked in the same situation for eighteen years, and for the last few days had been busy among some primula obconica, working with the shirt sleeves rolled up. The inflammatory condition on the neck and face had evidently been caused by rubbing those parts with the hands. I prescribed a lead lotion for him and he recovered in a few days. I also advised him not to touch the plants again with the naked hands, which advice he has followed and he has remained quite free from the complaint.

I am, Sirs, yours truly,

Bradford, April 7th, 1896. A. GRAY, M.B. Glasg.

Anxious.—The case supposed is not one which would necessarily come before the General Medical Council. A resident unqualified assistant is not so likely to bring his principal into a violation of the rules indicated by the Council as one resident outside. But apart from this aspect of our correspondent's plans he will forgive us for saying that they seem to us open to objection in an ethical respect. He does not say whether the former principal of his relative and unqualified assistant has sold his practice. But if so it is clearly not right for our correspondent to take an unqualified assistant whose popularity with the patients of his former employer might be used to draw patients from the practice. We submit to him that he should reconsider this arrangement apart from any fear of the action of the General Medical Council.

A SKIN AFFECTION PRODUCED BY WORKING IN TEAK.

To the Editors of THE LANCET.

SIRS,—I shall be obliged if you or any of your readers can inform me whether carpenters working in teak occasionally suffer from a skin affection very similar to that described as resulting from handling primula obconica and affecting the face and arms.—I am, Sirs, yours truly,

April 12th, 1896. H. N. A.

IMPURE TARTARIC ACID.

AT Devizes, on March 19th, the manager of a tea company's stores was summoned for selling a quantity of tartaric acid on Feb. 14th which was not of the nature and substance demanded. The analyst for Wiltshire stated that the sample contained 45 per cent. of pure tartaric acid, 51 per cent. being a compound of a crude acid, and there was a residue of 3 per cent.; he added that the sample, although very impure, was not injurious to health except in certain cases where it might be used medicinally and fail in the purpose intended. For the defence it was contended that the company had received a warranty from the wholesale firm supplying the acid that it was "of good mercantile quality and guaranteed genuine English make." The Bench said that the defence had failed both with facts and the law, and the defendant was fined £3 13*s.* 6*d.*

X. Y. Z.—Our correspondent is at liberty to undertake other work and would not thereby forfeit his diplomas. The profession, however, is a jealous mistress—once desert her and it will be difficult to reclaim her.

A QUESTION OF ETHICS.

To the Editors of THE LANCET.

SIRS,—I shall be obliged if you will advise me how to act towards a professional brother under the following circumstances. During the last few months I have been attending a very old lady who suffered merely from the usual infirmities of old age. I used to call to see her probably about once a fortnight. I heard to-day from her daughter (who called to pay my fees) that she died a week ago, and that on the day of her death a medical man, who happened to be passing the house, was called in and found her dying, and told them to send down to his house for a certificate of death, for which they paid one shilling. The daughter told me that the medical man was told that I was in attendance and he said he would communicate with me. I have not heard from him, though I have seen him and exchanged greetings with him almost daily since.

I am, Sirs, yours truly,

March 30th, 1896. F. L. HALLUCIS.

*** The facts are very remarkable as detailed by our correspondent, who, of course, was the right person to have filled up the certificate. We can offer no explanation of the conduct of the practitioner who was called in. The kindest thing our correspondent can do is to see him and discuss with him the ethics of the situation, of which he seems to have singular views. We should be pleased to receive any information that places his conduct in a different light, and it is always well to remember that the friends of patients sometimes err in their account of what has happened.—ED. L.

Mr. W. O. Hanlan is thanked for his communication (enclosing a copy of his letter to the Medico-Chirurgical Society of Glasgow) and his eloquent little hymn. The process alluded to is physiological, not pathological, and the main conclusion of the writer is untenable, we think; but that it would be desirable that more persons understood the hygiene of domesticity before marriage is undeniable, as it is undeniable that a widespread ignorance on such topics has led to the loss of life of many infants.

"ADVERTISING DENTISTS."

To the Editors of THE LANCET.

SIRS,—I have noticed your remarks anent the above, also Mr. Jones's reply, in which he states the Royal College of Surgeons in Ireland is quite capable of looking after itself. This statement I deny, and I state further that the said College shamefully neglects the dignity of its Licentiates in Dental Surgery. Let me here state a case. A friend of mine wrote not very long ago to the College informing it that one of its Licentiates was advertising broadcast a so-called American dentists' association, and had in a prosecution case admitted he was the proprietor, although the name of a non-licentiate only appeared as manager on the various bills and books. The reply my friend received from the College after a lapse of time was to the effect that the individual had promised not to repeat such conduct. Nevertheless, from that day to this pamphlets, books, and advertisements of the association still continue to be sent out broadcast, and the offender still defies the Royal College of Surgeons in Ireland.

I am, Sirs, yours faithfully,

April 13th, 1896. FAIRPLAY.

Enquirer.—We have already dealt with the publication which our correspondent forwards us. The coupon is, of course, the most objectionable feature.

Leytonstone is thanked for his communication. We have noticed the report in a leading article.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Somerset County Herald, Keighley News, Alnwick Gazette, Doncaster Chronicle, Carlisle Journal, Manchester Courier, Oban Times, Hereford Times, Whitby Gazette, Wakefield Free Press, South Wales Daily News, Cleckheaton Guardian, East Anglian Daily Times, Derby Standard, Chester Courant, Glasgow Herald, Derry Standard, Bradford Observer, Dundee Courier, Halifax Guardian, Bridgwater Independent, Sussex Daily News, Barnsley Independent, Newcastle Leader, Wolverhampton Chronicle, Bristol Times, Sheffield Independent, Alcester Chronicle, Birmingham Post, Freeman's Journal, Huddersfield Chronicle, Western Morning News, Leicester Post, Eastern Evening News, West London Observer, Times of India, Pioneer Mail, Builder, Yorkshire Post, Edinburgh Evening Dispatch, Bristol Mercury, Architect, Scotsman, Liverpool Daily Post, Sanitary Record, Leeds Mercury, City Press, Mining Journal, Local Government Chronicle, Weekly Free Press and Aberdeen Herald, West Middlesex Standard, Reading Mercury, Boston Independent, Hertfordshire Mercury, Surrey Advertiser, Gloucestershire Chronicle, Local Government Journal, Western Mail, Le Courrier de la Presse, Daily Free Press (Aberdeen), Leicester Daily Mercury, Newcastle Daily Journal, Evening News (Portsmouth), Bolton Evening News, Citizen, Shields Daily News, Citizen (Gloucestershire), Cromer Post, Rossenda's Free Press, &c., &c.*

Digitized by Google

Communications, Letters, &c., have been received from—

A.—Dr. D. W. Aitken, Edin.; Dr. J. W. Allen, Glasg.; Lt.-Col. Hon. W. H. Allsopp; Messrs. Arnold and Sons, Lond.; Army Medical Dept., Lond., Sec. of; Assn. for the Suppression of Street Noises, Lond., Hon. Sec. of; Assn. for the Supply of Pure Vaccine Lymph, Lond., Sec. of.

B.—Dr. P. M. Braidwood, Coleshill; Dr. G. Butlers, Kempton; Surg.-Major W. Beevor; Mr. M. A. Boyd, Dublin; Mr. M. Blok, Lond; Mr. C. J. Bond, Leicester; Mr. P. A. Bradshaw-Isherwood, Ramsgate; Mr. L. A. Bidwell, Lond.; Mr. G. Buxey, Southampton; Mr. H. A. Bridgman, Lond.; Messrs. A. and C. Black, Lond.; Messrs. W. H. Bailey and Son, Lond.; Messrs. Burgoyne, Burbidges and Co., Lond.; British American Ball-Nozzle Co., Sec. of.

C.—Dr. T. F. Chavasse, Birmingham; Mr. A. S. Collin, Lond; Mr. R. J. Cowen, Lond.; Mr. M. S. Constable, Stockholm; Mr. J. F. Colyer, Lond.; Mr. T. A. Collinson, Lond.; Messrs. Cassell and Co., Lond.; Messrs. Crossley, Moir and Co., Lond.; Messrs. J. D. Cooke and Co., Worcester; Canadian Advertisement Agency, Lond.

D.—Dr. C. Dukes, Rugby; Dr. C. H. Dyer, Cleckheaton; Mr. H. M. Draper, Hemel Hempstead; Mr. T. Dixon, Lond.; Messrs. W. Dawson and Sons, Lond.; Messrs Dring and Fage, Lond.; The F. A. Davis Co., Philadelphia; Delta.

E.—Dr. G. C. Elliot, Edin.; Mr. R. Ellis, Newcastle-on-Tyne; Messrs. Eason and Son, Dublin; Electric Photo Printing Co., Nottingham, Publisher of; Emigration Home for Destitute Little Girls, Lond., Sec. of.

F.—Dr. T. R. Fraser, Edin.; Fides, Lond.

G.—Dr. J. Galloway, Lond.; Mr. H. B. Gardner, Lond.; Mr. A. Greenham, Shanklin; Mr. J. H. P. Graham, New Brighton; Glasg. University, Sec. of; Grafton Galleries, Lond., Sec. of.

H.—Dr. S. Hyde, Buxton; Dr. L. N. Harding, Brighton; Dr. A. Haig, Lond.; Dr. W. A. Hollis, Brighton; Dr. F. de Havilland Hall, Lond.; Mr. Victor Horsley, Lond.; Mr. J. Harper, Nondweni, Zululand, S.A.; Mr. J. H. Haywood, Manchester; Mr. R. Hingston, Liskeard; Mr. T. W. Hannaford, Lond.; Mr. W. H. Haley, Lond.; Messrs. A. Hurst and Co., Lond.; Messrs. Haasenstein and Vogler, Köln; Messrs. Henderson and Birkett, Gateshead; Messrs. J. Haddon and Co., Lond.; Hanover Inst. for Nurses, Lond., Proprietress of; Hunterian Society, Lond., Hon. Sec. of; Home Dept., Under-Secretary of State of.

I.—Dr. A. Innes, Lond.; Ings House Nurses' Co-operation, Lond., Sec. of; International Med. Congress, Dunedin, Sec. of.

J.—Sir George Johnson, Lond.; Mr. F. B. Jessett, Lond.; Mr. R. Johnson, Lond.; Mr. T. W. C. Jones, Lond.; Messrs. A. Jubb and Son, Huddersfield; Jeyes' Sanitary Compounds Co., Lond., Sec. of.

K.—Dr. W. R. Kingdon, Lond.; Dr. T. N. Kelynack, Manchester; Dr. Norman Kerr, Lond.; Dr. E. Kingscote, Salisbury; Dr. B. C. Kelly, Carlisle; Mr. G. M. Kober, Washington; Mr. R. C. B. Kerin, Lond.; Mr. B. Kühn, Lond.; Messrs. R. A. Knight and Co., Lond.; Messrs. Kleinow and Co., Salisbury.

L.—Dr. J. F. Little, Lond.; Dr. R. Lee, Lond.; Dr. P. Luff, Lond.; Monsieur A. Lorette, Paris; Miss Lucas, Witham, Essex; Messrs. Lear and Son, Malvern; Liquor Carnis Co., Aston Clinton.

M.—Dr. J. Macintyre, Glasg.; Mr. F. Mason, Lond.; Mr. S. Moritz, Manchester; Mr. T. M. Madden, Dublin; Mr. P. Möller, Lond.; Mr. R. Manning, Dublin; Messrs. Macmillan and Co., Lond.; Messrs. Mackey, Mackey, and Co., Lond.; Mutual Life Assurance Co. of New York, Lond., Sec. of.

N.—Dr. E. F. Neve, Cashmere, N.W. India.

O.—Mr. W. P. O'Hanlon, Milton; Mr. C. A. P. Osburne, Hythe, Kent; Ormskirk Rural District Council, Medical Officer of; Od Chemical Co., New York, U.S.A.

P.—Mr. F. Powell, Lond.; Mr. Y. J. Pentland, Edin.; Mr. E. P. Paton, Lond.; Mr. Oliver Pemberton, Birmingham; Mr. E. P. Pentong, Middlesborough; Messrs. Parke, Davis and Co., Lond.; Prudential Assurance Co., Lond.

R.—Sir B. W. Richardson, Lond.; Dr. R. R. Rentoul, Liverpool; Dr. H. D. Rolleston, Lond.; Dr. A. Routh, Lond.; Mr. Sydney Rowland, Lond.; Mr. Redpath, Newcastle-on-Tyne; Mr. H. J. Rice, Sandbach; Messrs. J. Robinson and Son, Southgate; Messrs. G. Richardson, Son, Cook and Buchanan, Manchester; Messrs. J. Richardson and Co., Leicester; Messrs. Robertson and Scott, Edin.; Royal British Nurses' Assn., Lond., Sec. of; Roads Improvement Assn., Lond., Hon. Sec. of; Royal College of Surgeons, Dublin, Registrar of; Royal Meteorological Society, Lond., Assist. Sec. of; Rebman Publishing Co., Lond., Sec. of; Rector, Courteenhall; Reader, Leyton.

S.—Dr. P. C. Smith, Lond.; Dr. J. A. Shaw-Mackenzie, Lond.; Dr. F. H. Smith, Lond.; Dr. D. Smart, Liverpool; Mr. B. Salisbury, Marlborough; Mr. H. Sell, Lond.; Mr. G. H. Sutton, Newport; Herr R. Siebler, Berne; Messrs. S. Smith and Co., Lond.; Messrs. G. Street and Co., Lond.; Messrs. Street Bros., Lond.; South Devon and E. Cornwall Hosp., Plymouth, Hon. Sec. of; Sanitary Institute, Lond., Sec. of; Society for the Relief of Widows and Orphans of Medical Men, Lond., Sec. of; St. George's Hosp., Lond., Sec. of; St. Luke's Hosp., Lond., Sec. of; *South Wales Argus*, Newport, Editor of; Sheffield General Infirmary, Sec. of; Saanbach's News Exchange, Mainz; Semper Vigilans; S. P. P., Southsea; Statim, Lond.

T.—Dr. A. Tuxford, Boston; Dr. F. S. Toogood, Lond.; Mr. H. P. Tattersall, Blackburn; Mr. W. T. Thomas, Liverpool; Mr. G. C. Taylor, Stafford; Mr. Atwood Thorne, Lond.

U.—University College, Bristol, Dean of.

V.—Dr. G. L. Vintras, Lond.; Vegetarian Society, Lond., Sec. of.

The Hunterian Lectures
ON
INFANTILE SYPHILIS.

Delivered at the Royal College of Surgeons of England on March 23rd, 25th, and 27th,

BY J. A. COUTTS, M.B. CANTAB., M.R.C.P. LOND.,
PROFESSOR AT THE COLLEGE, AND PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN.

LECTURE III.[1]

MR. PRESIDENT AND GENTLEMEN,—The lesions of the osseous system in inherited syphilis are of great clinical interest. The due appreciation of their frequency and importance may fairly be claimed for modern observers. As late, indeed, as 1856 Diday writes that "the annals of science offer at most five or six well authenticated instances of them." These words of Diday and the reticence on the subject by the authorities of his day would seem inexplicable in the face of our present experience did it not appear by their writings that almost the sole affection of the osseous system Diday's contemporaries regarded as syphilitic was the presence of suppurating nodes on the long bones. Now, nodes on the long bones, whether leading to suppuration or not, are rarities in infants with inherited syphilis, and the non-discovery of them no doubt led to the erroneous impressions of Diday and others. Mr. Hutchinson states that he met with a few instances of nodes on the long bones in infants early in his career and, I gather, does not regard them as so very uncommon. Other writers, too, describe them as not infrequent, but that, being evanescent, they are often overlooked. This is as it may be, but careful and prolonged search has not enabled me to come across an instance of them in a child younger than eighteen months. In older children they are occasionally found in association with Hutchinsonian teeth and interstitial keratitis. They usually occupy the same situations as the nodes of the adult acquired form, but have seemed to me less tractable to the influence of iodide than these last.

If nodes are rare on the shafts of the long bones they are far from being so on the bones of the skull, for the researches of Parrot have clearly established the periosteal origin of the well-known cranial bosses occurring in inherited syphilis. These may appear in many places on the skull, but are certainly more frequent on the frontal and parietal bones, close to the margins of the anterior fontanelle. With regard to the contention as to what really constitutes a syphilitic type of skull in infants, I would state my conviction that the natiform skull of Parrot, with the four bosses closely surrounding the anterior fontanelle, is undoubtedly syphilitic, and in this I am happy in being confirmed by Dr. Eustace Smith. The subsequent changes in the skull brought about by rickets being superadded to syphilis have led, I believe, to a confusion amongst observers. But the cranial bosses in rickets are confined to accentuations of the frontal and parietal eminences. Mr. Macnamara has, moreover, in his interesting work on the bones and joints, shown that in extensive syphilitic disease of the bones of the skull the frontal and parietal eminences are the only parts that escape. In early cases, then, we have the means of distinguishing the syphilitic from the rachitic type of skull. But rickets is so frequent a complication of inherited syphilis that after the age of six months we are apt to get a mixed type of skull, with corresponding difficulties as to the part played by the different factors in its causation. If I ventured to criticise the classical description by Mr. Hutchinson of the later stages of inherited syphilis, it would be that the type of skull he associated with this complaint is really due to rickets following upon it. The cranial bosses in syphilis do not often last beyond the first year of life and leave no traces of their former presence, and, moreover, do not affect the situations of the frontal and parietal eminences.

As with the type of skull, the connexion between inherited syphilis and rickets has been one of discussion. The explanation of the frequent association of the two complaints would seem to me a natural and simple one. Rickets is a disease of mal-nutrition which may own many causes for its production. Amongst these, possibly, no factor is more powerful in this way than syphilis, and thus the vast majority of syphilitic infants incur a greater or less degree of subsequent rickets. The contention of Parrot, that every case of rickets has a foundation in syphilis, is to me, as with most others, inexplicable and utterly untenable. In only one case have I seen suppuration ensue upon a node on the skull. Here a tender swelling over the frontal bone occurred in a syphilitic infant about six months old, with redness and infiltration of the overlying skin. The skin gave way in a short time, and the bone beneath rapidly necrosed away, opening up the cerebral membranes; mercury, iodide, and the cautery alike failed to arrest the progress and the child died from abscess of the adjacent brain. Dr. Barlow lately mentioned that he had seen two cases of a like formidable character, but I am not aware whether he has published them or not.

By far the most important and frequent osseous affection in inherited syphilis is the inflammatory one occurring in the epiphyses and in the junctions between them and the rest of the bones. First described by Wegner in 1870, his researches have been confirmed and extended by Taylor of New York, Dr. Barlow, Dr. Lees, and many others. According to Wegner, there is found in the bones of new-born syphilitic infants and young children a morbid process taking place at the point of junction of the cartilage of the epiphysis with the diaphysis. This consists of a proliferation of the cells of the cartilage along with a retardation of ossification in its already calcified structure. At the same time this proliferation of the cartilage cells interferes with the existing blood-vessels, and the formation of new ones takes place imperfectly or is altogether arrested. As a consequence of this interference with the bloodvessels the cartilage cells themselves suffer in their nutrition and undergo atrophy or fatty change. The result of this morbid process is seen on section as a narrow, somewhat jagged line of yellowish or orange colour running along the line of the epiphyseal cartilage. This appearance, according to Wegner, is due to necrotic tissue separating the diaphysis from the epiphysis, and a further suppurative complication may lead to a complete detachment of the latter from the shaft of the bone. Taylor of New York confirms this appearance, but he—and in this he is supported by Waldeyer and Köbner—regards the yellow zone not as a necrobiosis due to deficient vascularity, but as a gummatous process due to the enormous proliferation of new cells, which by compressing the vessels lead to the destruction of the intervening tissues and the consequent separation of the epiphysis from the diaphysis. Whether Wegner's or Taylor's is the correct interpretation of the epiphyseal change is of minor moment; both are agreed as to the frequency and importance of the result produced. Along with the other changes just described the ossification of the epiphyseal cartilage proceeds irregularly, and the cartilage cells, which in health are arranged in rows, are disarranged, or are completely disintegrated and replaced by groups of smaller cells.

Such, in brief, is a summary, mainly from Henoch, of the pathological disturbances occurring in the epiphyseal cartilages upon which most modern German writers lay especial stress. It is claimed that the morbid process always appears in several places simultaneously, particularly often at the lower end of the femur, in the bones of the legs and forearms, and in the ribs; sometimes in all the long bones together. It is not necessarily confined to the larger bones, however, for it is now known that syphilitic dactylitis in reality commences with disease of the epiphyseal ends of the phalanges. Wegner, who first described this epiphyseal disorder, says it is almost constant in the bodies of infants suffering from inherited syphilis. Kassowitz, who admits its extreme frequency, had nevertheless met with a few cases where it was absent. Waldeyer, Köbner, and Fränkel describe it as being present without exception in every case of inherited syphilis, and the first two state that even when there are no naked-eye changes in the epiphyses these may be recognised with certainty by the microscope. Birch Hirschfeld, too, writes as if the absence of epiphyseal disorder were the surest proof of the freedom of the infant from syphilis. Most of the modern German authorities, in fact, would seem to regard this affection of the epiphyses as pathognomonic and distinctive of inherited syphilis, and to regard its non-discovery as conclusive evidence of freedom from it. In the

[1] Lectures I. and II. were published in THE LANCET of April 11th and 18th, 1896, respectively.

Digitized by Google

English text-books much less attention is paid to it. This possibly arises, however, from the subject not having received the general notice that its importance deserves, owing to a non-appreciation of its prevalence.

Whether it be as frequently present as a pathological condition as some German writers allege or not, there is a consensus of opinion that this epiphysitis only calls for consideration as a clinical symptom in exceptional instances. In its milder forms it can sometimes be diagnosed by the pain elicited by pressure over the epiphyses of the long bones, more especially the lower ones of the humeri and bones of the orearms. But pain is no necessary accompaniment of syphilitic epiphysitis; and there may be considerable swelling of the epiphyses of several bones with no obvious sensory disturbance. This swelling of the epiphyses, with or without pain, as the lesion giving rise to it is a congenital one, may appear in infants of any age. When the enlargement of the epiphyses is of any considerable size, however, it usually occurs in infants of from three to six months old, but is rare after the latter age. Some writers give criteria by which syphilitic enlargements of the ends of the bones are to be distinguished from rachitic ones in the same situations, but I cannot think confusion between the two conditions can often occur. The younger age of the syphilitic patients, the want of symmetry in the distribution of the bony lesions, the greater prevalence of the lesions in the bones of the upper extremity, and even here very often a predominance in one side over the other, along with the presence of other signs of syphilis, ought to be sufficient to prevent errors of diagnosis. Still, in children over the age of six months syphilis and rickets may occur together, and here it may perhaps be an impossible matter to duly apportion to each disease its share in the causation of the epiphyseal swellings.

Suppuration as a result of epiphyseal disease of the long bones is rare in infants under a year old, and I have only known two or three examples of it. In older children suppuration over the ends of the long bones is, perhaps, commoner than in young infants, owing possibly to walking and other uses of the limbs proving prejudicial to a previous epiphysitis not entirely cleared up. A symmetrical suppurative epiphysitis in children between one and three years old is to me sufficient to warrant a strong suspicion of syphilis for its causation. In contradistinction to the case of the long bones, suppuration arising from epiphysitis of the phalanges, "syphilitic dactylitis," is not very rare. Like Mr. Hutchinson, I have only seen it in connexion with the bones of the fingers, never with those of the toes. Dr. Colcott Fox has, however, published a case where it occurred in the foot. On all these points regarding suppuration I speak with some diffidence, as such cases come more appropriately under the care of the surgeon than that of the physician. Like suppuration, separation of the epiphyses of the long bones is rare, and my experience of such cases is an extremely limited one. Dr. Barlow has lately called attention to the deformities of the limbs that may result from it owing to the awkward angles at which the epiphyses may rejoin the shafts.

By far the most interesting condition associated with epiphysitis is the anomalous one known as syphilitic "pseudo-paralysis," in which one or more of the limbs lie cold, wasted, and flail-like by the sides of the body. I have associated this "pseudo-paralysis" with epiphysitis because the generality of writers have ascribed the muscular wasting to disuse, owing to the pain ensuing on motion from the presence of epiphyseal swellings. Henoch has thrown doubts on this origin of the disorder, however, and with these I agree. It is quite possible to have marked wasting and complete immobility of the limbs in a syphilitic infant without any obvious epiphyseal swellings and with an entire absence of pain. In two cases of "pseudo-paralysis," moreover, having a perhaps exaggerated fear of epiphyseal separation, I had the affected arms confined in splints. Under the use of mercury the infants concerned recovered power and muscular tone, although their arms were rigidly fixed. I cannot, then, hold mere disuse accountable for the muscular wasting and paresis. As a possibility I would suggest a peripheral nerve origin for this "pseudo-paralysis" due to the epiphyseal disease, and its being, perhaps, akin to the nervous disorder Dr. Ord has shown may arise from primary joint trouble. Bednar, who would seem to have been exceptionally fortunate in meeting with "pseudo-paralysis," for he found it in nineteen out of sixty-eight cases of inherited syphilis, ascribed it to a syphilitic myositis. It is essentially a complication of the earlier stages of inherited syphilis, the limits of age during which I find records of its occurrence being one week and eight months. At the first-mentioned age it was noted in a case under Dr. George Ogilvie's care and at the latter in one under Henoch's care. It is possible, however, that more careful search would enable me to find it recorded at a later age than the one mentioned. My own cases, amounting to perhaps a dozen, all occurred in infants under the age of three months, most of them, indeed, in infants less than six weeks old. In several the paralysis was the earliest symptom of inherited syphilis and preceded the more unequivocal ones by an appreciable interval. In all my cases the arms alone were affected and in only three did the complaint attack both limbs; in these three, moreover, the one arm was affected before the other. In Bednar's nineteen cases the arms were affected sixteen times, the legs once, and all the limbs twice. All observers are agreed as to the special tendency for the arms to suffer and that these suffer first even in the cases where other limbs are subsequently affected. What other factors besides syphilis are necessary for its production and its pathology are still problems requiring solution.

Turning from the symptoms of the inherited to those of the acquired forms of syphilis in infancy is to enter upon a subject about which there have been the most ardent debate and controversy. That accidental syphilis is rare in infants, as they are not exposed to the ordinary channels in which infection is incurred in adults, will not be denied. Much of the uncertainty and contention regarding its manifestations undoubtedly arise from the lack of clinical material necessary for forming more definite conclusions. No one observer has seen a sufficient number of cases to entitle him to speak dogmatically on the question. Notwithstanding this, there has been dogmatism more than sufficient on the part of most writers on the subject, and I fear that only recently I may have laid myself open to the same charge. In what follows, then, I should preliminarily state that any conclusions I may draw have been formed on a limited experience of eight cases of acquired syphilis in infants under a year old, although this experience has been supplemented to some extent by a larger one of acquired syphilis in children of older age. It may well be, then, that further opportunities may lead me to largely modify my present views concerning the acquired forms in infancy. The only difference Colles recognised between the acquired and inherited forms in infancy was the liability of the mother, as well as the nurse, to contract the former. In fact, he gives cases where healthy infants were contaminated by infected nurses and makes no distinction between the syphilis so acquired and that inherited from the parents. Most writers before and since his time have concurred in making no distinction between the acquired and inherited forms in infancy. Diday, however, would seem to have recognised a difference in the two forms, for he writes: "Congenital syphilis does not assume either the behaviour, the progress, or the concatenation of symptoms of the syphilis of adults. A little observation suffices to show that we have here two diseases, analogous but not identical; that if their prognosis differ, it is less on account of the age of the subjects they attack than from the nature and character peculiar to each of them. Producing previous to any characteristic symptom a kind of atrophy or stunted condition of the whole economy, breaking out afterwards at a hundred points at the same moment, accompanied from the first by visceral lesions foreign to acquired syphilis, contagious by its slightest symptoms, congenital syphilis can only be compared to itself, and it is from its energy, much more than from the weakness of its victims, that we must ask the secret of the special dangers which it involves." Further, again, Diday writes: "Syphilis, so often fatal in new-born children when inherited from their parents, scarcely ever compromises their existence when it has been accidentally innoculated from a primary chancre in an adult." Whilst not agreeing with Diday as to the special virulence of infection attaching to congenital syphilis, I am at one with him regarding the differences between it and the acquired form, and especially so as to the much diminished constitutional disturbance in the acquired form in infancy. Mr. Hutchinson has no separate description of the symptoms of the acquired form in infants, possibly because he deemed it unnecessary, but in writing of the inherited variety he says: "Excepting in the addition of 'snuffles' these secondary symptoms are much the same as those observed in the acquired disease." It is not a just assumption from this last that Mr. Hutchinson

Digitized by Google

denies the presence of "snuffles" in the acquired syphilis of infants, as his description of the acquired disease was drawn from that presenting in adults. If, however, his description be intended as universally applicable to the acquired form, whether in adults or infants, then the absence of snuffles in the last must be considered as a valuable criterion in differentiating them from cases of the inherited variety, where "snuffles" plays such a frequent and conspicuous part. According to Dr. Radcliffe Crocker, "Acquired syphilis in children and infants presents much the same symptoms and runs much the same course as in the adult, except that in very young children the bones at the junction of the epiphyses to the shaft are very likely to be the seat of inflammation." With regard to the similarity of the acquired form in infants to that in adults Kassowitz is in accord with Dr. Crocker, although he goes further in this direction than I gather the latter is inclined to follow. "When a healthy infant," Kassowitz writes, "is infected shortly after birth its syphilis does not differ from that of an adult, *but does so most markedly from that of a child of the same age with the inherited complaint. The difference between them, then, is one not merely due to age.*" Kassowitz has tabulated the differences between the inherited and acquired forms in infancy and his numeration is briefly as follows:—1. In the inherited form there is early involvement of the abdominal viscera, which involvement is often intra-uterine and may precede the skin eruption by months. In the acquired form any affection of the viscera is always a late symptom and seldom occurs. 2. In inherited syphilis there is a peculiar and characteristic affection of the calcifying cartilage and growing bone; this "epiphysitis" occurs early and may be intra-uterine. The early appearance and extensive distribution of this "epiphysitis" in inherited syphilis have no analogy in the acquired complaint. 3. In inherited syphilis there is frequently diffuse infiltration of the skin, especially of the face, soles, and palms. In acquired syphilis there is no such infiltration observed either in infancy or later age. 4. In inherited syphilis there is a peculiar characteristic appearance and distribution of eruption different from those obtaining in acquired syphilis in infancy. 5. In inherited syphilis vesicular eruptions are frequent, but are never observed in the acquired form. 6. In inherited syphilis prodromal coryza is almost universal, but is absent in the acquired complaint. Such are mainly the criteria by means of which, such a judicious and experienced writer as Kassowitz asserts, a distinction can be clearly made between the inherited and acquired forms in infancy. With most of the distinctions drawn by Kassowitz between the two forms of the complaint in infancy I personally agree. As minor details, however, I cannot regard a vesicular eruption as a common occurrence in the inherited form, nor can I, after reading Dr. Crocker's cases, lay the same stress as Kassowitz does on the difference between the manifestations of "epiphysitis" in the two varieties of the complaint. As far as my experience goes the commonest eruption in acquired syphilis in infants, as in adults, is the well-known roseola and its usual distribution, the same at all ages, viz., the front of the chest, the abdomen, and to a less degree the flexor aspects of the limbs. This syphilitic roseola, admittedly rare in inherited cases, was the form of eruption in seven out of my eight cases. In the remaining one, an infant that had acquired a chancre on the back of the neck from kissing by a syphilitic aunt, and that had in its turn given its mother a chancre on her breast, a universal small pustular eruption broke out all over the body. Along with the rash, too, in most of my cases I found a condition of throat identical with that occurring in adult syphilis; this is in marked contrast with what happens in the inherited form, where the throat remains, as a rule, unaffected. The chief peculiarities of the symptoms, however, in acquired syphilis in infancy are the scantiness and evanescent nature of the eruption, which may be easily missed, and the subsequent early and luxuriant growth of condylomata. These peculiarities of acquired syphilis in children were pointed out by Henoch, who apparently did not deem its manifestations identical with those of the inherited form. Dr. Barlow informs me that he has found a difference in the appearances and distribution of the eruption in acquired syphilis in infants from that occurring in the inherited variety, and that his experience tallies with that of Henoch with regard to the appearance of condylomata in the former complaint. My colleague, Mr. R. W. Parker, too, emphatically asserts the resemblance of the acquired form in infancy to that in adult age, and the manifest points of difference in the symptoms to those occurring in the inherited form. In very rare instances it may be that the eruption of inherited syphilis may imitate that of the acquired form, so that a reliable opinion as to which of the two is concerned must be formed from other considerations than the mere rash and its distribution. In contrast to this, in no instance have I seen or learnt of the symptoms of the acquired complaint approximating to those of the typical ones of the inherited variety. I would freely admit, however, in spite of the evidence and authorities I have given as to the differences between acquired and inherited syphilis in infancy, that there is perhaps no one single symptom which would serve as an absolute mark of distinction between the two complaints. When all the symptoms are, however, taken into consideration I would contend that sufficient criteria exist in most cases to prevent confusion between them.

Of the primary chancre, a fundamental necessity for the existence of acquired syphilis in infants, I have as yet said nothing, preferring an attempt to point out the differences between the complaint and the inherited form apart from its consideration. There is, of course, no need to insist upon a chancre as the primary factor in the acquired syphilis of infants, as in adults, before my present audience. Only too often, however, within my personal knowledge, owing to reckless charges against public vaccinators and others, has occasion arisen for the insistence of a chancre and of the necessary incubatory periods in acquired syphilis in infants. When the fact is firmly grasped that such syphilis in infants runs the same course, both in its primary and secondary manifestations, as in adults, most of such charges will cease to be brought or seriously entertained. The vast majority of chancres in infants must, from the nature of the case, be situated on the skin or other external part of the body, and present the same conspicuous features in them that chancres do in adults in the same situations. With the minute examinations that infants undergo for "spot or blemish," usually twice a day, there is small chance in them for a chancre to be passed over by even the most careless mother, no matter how frequently they may be missed in adults. Even when a chancre has passed away, moreover, it leaves visible and tangible traces of its former presence, lasting for months or perhaps years, which are generally easy to find in an infant's tender skin. The sticklers for the rigidity of Colles' law universally allege, when supposed exceptions to it are brought forward, that such exceptions are cases of acquired syphilis in which the primary chancres have been missed. It is to me a remarkable coincidence that it is mainly in such cases where a presumption of acquired syphilis is made to uphold the law that such conspicuous objects as infantile chancres are missed and leave no traces behind them, and that there is a total lack of evidence as to the source of infection. In each one of my eight cases there was no difficulty in ascertaining the original site of inoculation.

Another special point about acquired infantile syphilis is its power of infection. This I propose to leave until I have dealt with the infectiousness of inherited syphilis, which I now proceed to do.

On no other point in syphilis has there been more contradictory teaching than on that of the infectious nature of the lesions of the inherited form. Whilst some authorities have described inherited syphilis as exceptional in the contagious property of all the lesions it engenders, others have denied the contagiousness of inherited syphilis at all. Since the works of Diday, however, his teaching has apparently been accepted as the standard one, and the extreme virulence of the contagion of inherited syphilis has been promulgated by most writers, many of whom I suspect in this instance were more influenced by the authority of accepted doctrine than by the result of their personal experience. The opinions of the older writers on the point are difficult to gauge, as they classed cases of transmission from infant to nurse with those of transmission from nurse to infant, and seemingly deemed any discrimination between the two classes as of little moment. Hunter, in the days when he still believed in the reality of inherited syphilis, denied the possibility of transmission from the infant to another person. The elder Cullerier and most authorities up to the time of Colles would seem to have agreed with Hunter on this point. When Colles, however, published his book in 1837 he rudely upset the prevalent belief in the non-contagiousness of inherited syphilis. It

Digitized by Google

was, according to him, the peculiar virulence of the contagion of infantile syphilis that distinguished this last from the adult type. It was not necessary, he wrote, for a woman to suckle a syphilitic infant to acquire the complaint from it—it was sufficient for any one to do so merely to dress, handle, kiss, or fondle such an infant. In fact, he would seem to have imagined the mere presence of such an infant as a menace to the unprotected and to have believed in a real "aura syphilitica" emanating from it. More than this, he again writes: "The members of the nurse's family may also contract the disease, and more easily than she, for this disease seems to acquire more force the further it becomes removed from its first origin." Most of Colles' personal observations are of little value now, as he indiscriminately mixed up cases of acquired and inherited syphilis in infants, and drew deductions from them as though they were of identical nature. He did not, moreover, acknowledge a primary chancre as a necessary part in the contraction of syphilis by an adult. For him to diagnose syphilis in a woman suckling an infected child it was sufficient that she had ulcers or other sores about the nipples, and he remarks the curious fact that in such cases the disease often limited itself to these manifestations on the breasts. Diday, following in the same steps as Colles, went even beyond the last, if possible, in his estimation of the power of contagion of inherited syphilis. "I have already stated," he writes, "and hope to prove it, that the lesions of congenital syphilis differ from those of ordinary syphilis by an infinitely greater power of contagion. And what is at the same time remarkable and deleterious in them is that they transmit the same property to the person who receives the disease from them." He considers this virulence of contagion so well established that if he saw a woman presenting signs of constitutional syphilis transmit them to her husband the suspicion would at once arise in his mind that they were congenital in character and derived from a child with inherited syphilis nursed by her. If, moreover, he learnt that a nurse had given syphilis to several men, he would consider that there were sure reasons that she had acquired the disease, not by coitus, but from suckling an infected nursling. He writes of the infection of nurses as being of daily occurrence, of thousands of examples of it being readily adducible, and he gives accounts where the presence of a single case of inherited syphilis has produced in healthy rural communities outbreaks of syphilis that can only be described as "volcanic," from the suddenness of their incidence and the numbers that were attacked. Notwithstanding the confidence and dogmatism with which Diday wrote, there were even in his own time authorities who differed strongly from him, and Ricord, the younger Cullerier, Bassereau, and others would seem to have regarded the contagion of inherited syphilis as a chimera. Maissonneuve and Montanier, too, declare that "doubt is no longer permitted" as to the non-contagiousness of inherited syphilis Diday quotes all these last named, and, in the face of their writings, it is difficult to appreciate the following remark of his. "All observers have pointed out the propagation of the symptoms by the slightest contact from the new-born child to the nurse, and it is not uncommon to see two or three families victims to the presence of a single syphilitic suckling." As to the reliance and value to be placed on Diday's opinion on the point, the following controversy is both instructive and interesting. "Remark well," Ricord writes, "that I do not absolutely reject this mode of transmission from the foster-child to the nurse, and from the nurse to the foster-child. I only say, without leaving the field of strict observation, and of the exact analysis of facts, that this mode of transmission is not yet proved." Diday rejoins, "I have no difficulty in acknowledging with him (Ricord) that among the clinical facts advanced in proof of this mode of contagion there is not one which is thoroughly demonstrative, there is not one in which the daily observations of the symptoms—on the one hand in the nurse, her relations, and those around her, on the other, in the child, its father and mother—render it evident that symptoms really constitutional have passed from the one to the other; but—and in this I regret to differ from Ricord—I am inclined to think that if the conclusive fact be wanting probable facts abound, and that to such an extent as to make up by their number for the absence of the former." In the face of his "thousand histories of infectious lactations furnished daily by experience," Diday's inability to adduce one single conclusive example is both startling and inexplicable. His evidence of the conveyance of syphilis by nurslings, too, is not convincing in the light of our present knowledge. "Primary chancres," he writes, "exist in a very small minority of cases of nurses infected by infants. Mucous tubercles form the earliest symptom in each." It is significant, too, in his cases, as in those of Colles, that the syphilis contracted by nurses from infected infants very often remained confined to the affected breast and never manifested itself by symptoms elsewhere. But the disparity between the dogmatism of Diday on the virulence of the contagion of inherited syphilis and the proofs he adduces for it is only one amongst many inconsistencies that are to be found in his writings. It may be said that, feeling as I do regarding some portions of these writings, I have devoted too much time to their consideration. But as Diday's views are still commonly held, and he is largely quoted, no one can afford to lightly ignore him. I will proceed to discuss at less length some more recent opinions on the important point at issue.

Henoch considers the occasional transference from infant to nurse as proven. In his own vast experience, however, he had never known an instance of it. Fournier writes as if the contraction of syphilis from cases of the inherited disease were extremely common and of daily occurrence. An infant with this complaint, he asserts, would not infect its own mother, but would almost infallibly infect a healthy nurse. In fact, Fournier would seem to be a living exponent of Diday's views as to the virulence of the contagion of inherited syphilis. Mr. Hutchinson says that if an infant suffering from inherited syphilis be suckled by a nurse free from taint, "the risk is great that a nipple chancre will result." But as he further says that he has only known "perhaps half-a-dozen" nipple chancres altogether, his words would seem to me to exaggerate the risk incurred, more especially when his large experience is taken into consideration. Most latter day writers are in accord with Mr. Hutchinson, and in recent text-books inherited syphilis is described as "eminently contagious," or in kindred words to the same effect.

At the present time there would seem to be a growing opinion that the virulence of contagion of inherited syphilis has been vastly exaggerated both in text-books and by authorities, and that the contraction of the complaint by a healthy person from a tainted infant is an extremely rare occurrence. Some two years back I published a case of supposed exception to Colles' law, the weak points in which were justly and forcibly dealt with by Dr. George Ogilvie. His latest description of it as "not absolutely conclusive" I think a decidedly appropriate one for the case. If this case be rejected, however, and the supposition that the infant was really suffering from acquired and not inherited syphilis be maintained then I have personally never known an instance where syphilis was contracted from an infant with the inherited complaint; and this in spite of many thousands of healthy children and adults having been exposed to infection from cases under my care. To ascertain if my experience was in any way exceptional in this respect I have made inquiries of present and former colleagues at the East London Hospital for Children, all of whom have had a large acquaintance with cases of inherited syphilis. The results of my enquiries are so much at variance with prevalent belief that I feel it incumbent upon me to give the names of the gentlemen I consulted, and this, I may state, is done with their full consent. My senior medical colleague, Dr. Eustace Smith, has only known one instance where syphilis was contracted from an inherited case, and this was one where an infant infected its own mother. The case was seen by the late Mr. Berkeley Hill, who demonstrated to his own satisfaction, but not to that of Dr. Smith, that the infant was suffering from acquired and not inherited syphilis. Dr. Smith still believes that the case was one of exception to Colles' law and apart from it has never known syphilis contracted from the inherited disease. Dr. Donkin, Dr. Dawson Williams, Dr. Arnold Chaplin, and Dr. J. A. Hayward have never known an instance where an infant with inherited syphilis has infected another person. Dr. Johnstone Campbell has known one case of exception to Colles' law, which he proposes to publish when at greater leisure, but no other example of infection from inherited syphilis has come under his notice. Dr. Radcliffe Crocker has known one instance where an infant with inherited syphilis contaminated its foster-mother and her daughter. Mr. R. W. Parker has stated that he had seen a case of exception to Colles' law, but no other example of infection from inherited syphilis. Messrs. L. A. Dunn.

Digitized by Google

W. H. Battle, and H. Betham Robinson have never known syphilis contracted from a case of the inherited disease, and present and past resident medical officers, Messrs. P. C. Phillips, Scott Battams, and Dr. E. H. Ware, reply to the same effect. Now the experience at the East London Hospital for Children of the gentlemen I have named added to my own represents a joint experience of some thousands of cases of inherited syphilis. These syphilitic babies in the East of London, too, are indiscriminately suckled by other women besides their own mothers, and are freely kissed and fondled by numerous persons who thus expose themselves to infection from this presumedly eminently contagious disease. That the sole result, as far as could be ascertained, of many thousands of exposures to infection should be only five examples of the incurrence of syphilis, and that of these four should assume the form of exceptions to Colles's law, seems to me noteworthy and surprising in the extreme. If, as usually happens, these four examples of exception to Colles' law be curtly rejected as unreliable, then I can learn only one instance where syphilis has been contracted from a case of the inherited complaint at a large children's hospital where inherited syphilis is rife amongst the infantile patients, and where adult women are frequently treated for the acquired disease. I have no reason, either, to suspect that our experience at Shadwell is peculiar. Dr. Barlow and many others of large experience tell me that they have never known the contraction of syphilis by anyone from an infant suffering from the inherited complaint. Lately I have pestered all my friends with questions on this point and as the outcome I have learnt of two other solitary examples of its occurrence. My friend, Dr. John Thomson of Edinburgh, tells me he knows a case where a lady contracted a chancre upon her lip from kissing a grandchild with inherited syphilis, the father of the infant having incurred the disease about three years before marriage. Dr. W. S. Colman, too, tells me he knows a case where a baby with inherited syphilis infected its nurse. But three cases go but a little way to justify the descriptions usually applied to the power of contagion of inherited syphilis, especially when the experience and standing in the profession of those from whom I inquired are taken into account. That inherited syphilis is occasionally contagious is certain, but it is equally certain, I would contend, that the virulence of such contagion has been grossly and vastly over-estimated. It is impossible to reconcile the experience of certain French writers in this respect with our experience in this country, even when the greater frequency of wet nursing in France is fully admitted. There are certain reasons, or suggestions rather, by which I think the infrequency of the contraction of syphilis from infants suffering from the inherited complaint can be partially explained. The syphilis in such infants, it must be remembered, dates from conception and not from birth, and at the age at which symptoms appear such a syphilis is generally of about a year's standing, and may have lost some of its pristine virulence during both uterine and extra-uterine existence. If the views I expressed in my first lecture, too, be considered as worthy of any consideration, then it may be that some product absorbed by the mother during her first pregnancy may influence the succeeding conceptions and thus largely modify the disease in the infants resulting from them and its power of contagion. In this way I should expect a first infant more likely to convey the disease to others than succeeding ones, and I have a general impression that the histories of recorded authentic cases of such infection confirm this opinion. That the power of infection is possibly in some measure confined to the first infants in a family may help to partially explain the rarity of infection. Another reason, and a much weightier one, for the infrequency of infection from inherited syphilis is the rarity of specific sores about the mouths of infants, a fact which has been pointed out by Dr. Colcott Fox, Henoch, myself, and others. Even when such sores do appear they are a comparatively late manifestation, seldom occurring before the age of six months, and by this period, in the vast majority of instances, both treatment and time have probably so modified the complaint that conveyance to others is either in abeyance or annulled. It may be that the nasal secretion and that of mucous tubercles are infectious, but as the latter are a late manifestation the same reasoning applies to them as to sores in the mouth, and there are obvious reasons why the nasal secretion is not often encountered. The reasons I have given are, I admit, totally inadequate for a full explanation of the extreme rarity of infection from inherited syphilis, and whilst I consider that rarity established other grounds for it than those I have suggested are still to be sought.

In marked contrast to the rarity of infection from inherited syphilis is its frequency from the acquired form in infants. Only one instance is within my personal knowledge where a syphilis acquired by an infant was not communicated to one or more persons brought into contact with the child. Numerous instances are on record, from the time of Ambroise Paré onwards, where infantile acquired syphilis has been the cause of severe outbreaks amongst relatives and friends. Recently I learnt of one in the east of London where acquired syphilis in a child spread to five others in the same family besides strangers. Some of the best authenticated cases, too, recorded by Colles and Diday, who contended for the greater virulence of the inherited form, occurred where numerous persons contracted the disease from an infant with the acquired disease. In fact, it would seem to me that what these writers really contended for was more the extra virulence of infantile syphilis generally than for any difference between those of the acquired and inherited forms. Although the presence of acquired syphilis in an infant is the more dangerous to the community at large, there is, I need hardly say, no difference in virulence between such a syphilis and that acquired by an adult. But the presence of the dread disease in an innocent-looking baby is so seldom suspected that generally one or more persons are contaminated before the truth is discovered—a condition of affairs that does not often occur in the case of adults. So nearly constant, however, is the infection from an infantile acquired case, and so extremely rare that from one of the inherited form, that, in the lack of other criteria, a diagnosis between the two varieties might almost be made from the presence or absence of infection in most instances.

The few minutes remaining at my disposal I will devote to some brief considerations of Colles' law. This law in reality consists of two separate parts, the one that the mother of an infant with inherited syphilis cannot contract the disease from her own child, and the other that such an infant would almost infallibly contaminate a healthy wet-nurse. The fact of the inclusion of this second proposition is generally forgotten by writers contending for the absolute validity of the law. In dealing with the contagiousness of inherited syphilis I endeavoured to show that this part of the so-called law is far from true. It may well be, then, that the main safety of the mother lies in the little liability of the infant to transmit the disease rather than in some protective quality residing in herself, due to the fact of her having borne a syphilitic infant. For my part I think both such factors possibly conduce to the safety of the mother. Is the first part of Colles' law absolute? Has an infant with inherited syphilis never contaminated the mother? In Colles' own practice, and in those of others since his day, cases have from time to time occurred which were apparently exceptions to the law. Some of these cases are so imperfectly recorded that discussion of them is hardly called for. Others, on the contrary, Dr. George Ogilvie writes, "are as conclusive as any recorded clinical facts can be." Fournier, somewhat grudgingly it would seem to me, admits the validity of some such cases, and he would appear to regard the subject of exceptions to Colles' law as of little practical importance on account of the extremely exceptional character of such exceptions. Mr. Hutchinson has lately stated that he not only admits the possibility but the probability of these exceptions. I am the more pleased at this admission in that it places him in accord with Fournier and other authorities in the matter, and that it is also in some sense a further justification for the belief in myself and others that we have actually met with exceptions to Colles' law. Mr. Hutchinson's sole contention is, I believe, that as yet no exceptions have been recorded worthy of trust. I am unwilling to differ from him, but I must state my conviction that Dr. George Ogilvie's admirable paper at the Royal Medical and Chirurgical Society is conclusive on the point. Granted the possibility of exceptions to Colles' law, ought such eminently infrequent occurrences to largely modify our practice in allowing apparently healthy mothers to suckle tainted infants? Personally, I should say decidedly not. In my second lecture I emphasised the importance of maintaining the nutrition of the infant, and for this purpose no factor is more essential than the mother's milk. If ever legislation for the many to the detriment of a limited few is justifiable, the case in question calls for it. Following in the same path as Henoch, the only limitations I would place on suckling by mother or wet nurse would be the presence of excoriations on her nipples

Digitized by Google

and that of ulceration or fissures about the mouth of the infected infant.

In conclusion I have to apologise for the disjointed and fragmentary character of these lectures. In reality they deal with only a very limited portion of the subject of infantile syphilis. Important questions, such as diseases of the nervous system, vaccinal syphilis, prognosis, treatment, and many others, I have preferred to altogether omit rather than to attempt to treat in a perfunctory manner. In fact, my selection has been manifestly based on controversial grounds rather than any other.

RHEUMATOID ARTHRITIS: ITS CLINICAL HISTORY, ETIOLOGY, AND PATHOLOGY.

BY GILBERT A. BANNATYNE, M.D. GLASG., M.R.C.P. EDIN.,
HON. PHYSICIAN TO THE ROYAL MINERAL WATER HOSPITAL AND TO THE ROYAL UNITED HOSPITAL, BATH;
AND
ARTHUR S. WOHLMANN, M.D., B.S. LOND.

With a Report on its Bacteriology

BY FRANK R. BLAXALL, M.D. LOND., D.P.H. CAMB.,
LECTURER ON BACTERIOLOGY TO WESTMINSTER HOSPITAL.

UNTIL quite a few years ago rheumatism, like gout, was almost universally regarded as a disease of "chemical" origin. Lactic acid, as a product of disturbed metabolism, played the part of uric acid in gout, and the possibility of a pathogenic micro-organism scarcely entered into the range of serious discussion. Even three years ago, when first we started on our search for the *materies morbi* of rheumatoid arthritis, the idea of an organism as a causative factor in any one of the group of "rheumatic" diseases seemed somewhat wild and improbable; but since then several suggestive papers, notably that of Newsholme,[1] have thrown fresh light on the subject, and have at least accustomed one to the idea that acute rheumatism may probably prove to be an acute specific disease caused by a definite pathogenic microbe. It was the close analogy of rheumatoid arthritis to tuberculosis that first suggested to our minds the possibility of a micro-organism as the cause of the disease; and, once started on that idea, the clinical symptoms, so difficult to account for on the usual nervous and other theories of causation, readily fell into their place in a natural and explicable sequence until long before we had actually found the organism we were quite convinced of its presence.

But at the very outset we were met by great difficulties in obtaining pathological material. Clinical material we had in abundance, but the opportunity of examining post mortem the joints of a patient suffering from rheumatoid arthritis was an event of such extreme rarity that we were forced to be content with the examination of synovial fluid obtained during life. And here, again, of course, came the difficulty that the number of cases of synovial distension honestly likely to be benefited by tapping was extremely limited, forming a very minute proportion of the hundreds of cases passing through our hands; in consequence there was great delay and we had often to wait months for fresh material. The cases from which our synovial fluid was, as a rule, obtained were those of rheumatoid arthritis in which there was great distension of a joint, generally the knee, occasionally the wrist or fingers, which did not yield to blistering and other medical means. In such a case, the skin over the joint having been made aseptic and a simple form of aspirator carefully sterilised, the needle was plunged into the joint and the fluid withdrawn. Often, although the joint seemed distended with fluid, none could be obtained in the aspirator bottle, but in such cases there would generally be found a drop of fluid or a plug of synovial membrane in the point of the needle which would be sufficient for our purpose. With a sterilised platinum wire various culture tubes were then inoculated on the spot, several coverslip preparations made of the fluid or membrane, and the fluid in the bottle retained for further examination in the laboratory. The limb was placed on a splint for a few days, the needle-wound being dressed with cyanide gauze, and slight pressure kept up with a bandage. The aspiration generally relieved the pain, but often the fluid would return requiring a second and sometimes even a third tapping. In no case was any injurious effect apparent on the joint. In the microscopic preparations so obtained we found in 24 cases out of 25 rheumatoid joints examined: (*a*) a micro-organism; (*b*) always the same organism, so far at least as size, appearance, staining properties, and behaviour in culture media were concerned; and (*c*) the organisms were present in considerable, sometimes in enormous, numbers. To Dr. Blaxall of the British Institute of Preventive Medicine, to whom we are very greatly indebted, we leave the task of describing, with fuller detail and with more practised hand, the appearance, the properties, and the life-history, so far as is at present known, of the microbe as found by him in the specimens of synovial fluid which we have sent him.

Before going on to discuss the etiology of rheumatoid arthritis let us make it perfectly clear of what disease it is that we are speaking. Probably in no department of medicine is there more hopeless confusion of nomenclature than in the group of so-called "rheumatic" diseases. An acute disease with its rapid onset, its definite course, and its tangible and immediate results can hardly fail to impress the observer; it is seized upon, studied, named, and classified. With a chronic disease, on the other hand, the wearisome chain of indefinite symptoms ends by wearing out alike the time, the patience, and the interest of the observer; and hence it is that under the heading of chronic rheumatism or of osteo-arthritis there are probably massed almost as many diseases as formerly there were under "fever" or "paralysis." Provisionally, then, we divide the rheumatic and allied groups as follows: (1) acute rheumatism, (2) chronic rheumatism, (3) gout, (4) rheumatoid arthritis, and (5) osteo-arthritis.

And here let us pause for a moment to point out what we mean by chronic rheumatism and by osteo-arthritis. To the heading of chronic rheumatism we would relegate those cases of stiffened, painful, and often distorted joints left as a sequel of acute or subacute rheumatism, the distortion in this case being apparently due to alterations in ligaments, tendons, and muscles, rather than to bony or cartilaginous changes, these latter, if present, being only secondary and due to superimposed osteo-arthritis. Absolutely indistinguishable clinically is the great group of cases in which there is no history obtainable of acute rheumatism, but which are yet known familiarly to everyone as chronic rheumatism. Whether these cases are really identical with the last is uncertain, but in the present state of our knowledge we must be content to allow them to remain in the same category.

It is when we come to osteo-arthritis that we begin to tread on uncertain ground. In the official nomenclature rheumatoid arthritis and osteo-arthritis are used as interchangeable terms for the same disease, but of late, with the further differentiation of the clinical features, there has been a growing tendency to retain the term rheumatoid arthritis for the specific disease we are about to describe and to keep osteo-arthritis for the more common mechanical condition characterised by lipping of bone, osteophytic growth, and erosion. As it seems a pity to attempt to add fresh words to our nomenclature we have retained the term rheumatoid arthritis for use in this narrower sense. By osteo-arthritis, then, we mean a local joint condition in which we find erosion of cartilage, thickening, eburnation, and lipping of bone, with or without fluid effusion. These changes may arise in a joint injured by accident, by occupation, or by the mere wear and tear of life; in such cases the affection may be a mon-arthritis, or, if multiple, asymmetrical, and picking out the joints in a definite manner and according to well-known physical laws, as shown long ago by Arbuthnot Lane, a summary of whose views will be found in a recent number of the *Clinical Journal*; or they may appear to be merely secondary changes ensuing in a joint already damaged by rheumatism, by gout, or by rheumatoid arthritis. In the latter case the joints involved may be multiple and the disease may appear to exhibit a quasi-symmetry. The condition appears to be purely local, and, except in so far as pain and inactivity hamper the functions, the rest of the

organism would seem to be absolutely unaffected by the disease.

Turning now to rheumatoid arthritis, we find a very different state of affairs. It is a "constitutional" rather than a local disease; the whole organism is affected; the joint condition is by far the most important *symptom*, but it is only a symptom, and not the whole disease. In contradistinction to osteo-arthritis, rheumatoid arthritis is a disease of women rather than of men (of 100 consecutive cases taken at random 85 were females and 15 were males); of comparative youth rather than of age (the average age of the above series of cases at the commencement of the disease was twenty-eight, the eldest sixty and the youngest four). There would, however, appear, as pointed out by Fortescue Fox and others, to be two periods of greatest frequency of onset: one—and this embraces the larger number of cases—of early adult life, say from eighteen to twenty-five; the other the period of the climacteric. With respect to the family history we are unable to make any very definite statements. Hugh Lane[2] maintained that the disease is caused by the amalgamation of the hereditary taints of gout and tubercle. From our own experience we are unable either to confirm or refute this statement. In the case of a child who died from rheumatoid arthritis we were fortunate enough to secure a family history through four generations on the mother's side and two on the father's. In this case, of eight brothers and sisters, one died in infancy and six were very "delicate"; the mother suffered severely from rheumatism, while her three sisters had acute rheumatism and heart disease; the grandmother had "rheumatism," while the great-grandmother died from phthisis. On the other side, the father was normal; the grandfather had "rheumatism." Anyone, however, who has gone into the subject of family history in hospital patients will admit the extreme unreliability of the statements obtained. Rheumatoid arthritis is predisposed to by any debilitating cause, more especially by anything particularly weakening the resisting power of the joints. Of all predisposing causes acute rheumatism seems to be the most potent (of the above series of 100 cases 38 gave a history of previous acute rheumatism). But here two obvious fallacies have to be taken into account. The onset of the disease if at all acute, as is not unfrequently the case, may be mistaken for a mild attack of acute rheumatism; while, on the other hand, in the rheumatic fever of childhood the joint symptoms are often so little pronounced that the nature of the disease is entirely unsuspected. In a very large proportion of the cases we find a history of menstrual disturbance, amenorrhœa, dysmenorrhœa, or too frequent menstruation; in a still larger proportion the menstrual trouble comes on after the rheumatoid disease has well developed.

Amongst other debilitating causes should be mentioned the chlorosis of puberty, rapid child-bearing, prolonged lactation, worry, over-work, ill-feeding, and such diseases as typhoid fever. As a rule, the first manifestation of the disease is the gradual onset of a painful spindle-shaped swelling of the proximal interphalangeal joints of the ring- and middle-fingers; sometimes the pain precedes the swelling, sometimes the swelling precedes the pain. Usually both hands are affected within a few months of each other. Occasionally the disease commences in the wrists; rarely in other joints—e.g., the knee. Spreading fairly symmetrically from joint to joint the disease involves, in definite order of frequency, the wrists, the rest of the fingers, the articulations of the cervical vertebræ and of the jaw, the knees, elbows, ankles, tarsal-joints, and shoulders. The other joints usually escape, though the hips occasionally suffer, and we have seen the toes spindle-shaped like the fingers, though this is rare. The thumbs and great toes generally escape.

Clinically the joints may be affected in one of two ways. There may be a deceptive appearance of bony nodular enlargement; this is most noticeable about the finger-joints and is usually due to tense distension of small synovial pouches connected with the joint cavity; firm pressure with the finger will show the true nature of these swellings, while unexpected confirmation of this opinion has recently been furnished by the application of the Roentgen rays, but more often there is a soft, doughy-looking swelling blurring the outlines of the articulation. In such a case there appears to be little or no fluid in the joint, but the synovial membrane is greatly thickened and swollen, while the ligaments and fasciæ about the articulation are softened and infiltrated. Bony grating is not obtained in such a joint; it is only later, when secondary osteo-arthritic changes have taken place, that the harsh grating of erosion is obtained. The skin over an affected joint generally feels distinctly hot to the touch, and if the process is at all acute there may be a distinct blush closely resembling that of acute rheumatism. The pain is usually severe, fluctuating considerably, and in some cases apparently largely influenced by changes of weather. The body temperature is generally raised about a degree at night, falling to normal in the morning. In children, in whom the disease is always more acute, the temperature may rise to 101° F. or even more every evening. Another peculiarity of the disease in children, to which Dr. G. F. Still first drew our attention, is the frequency with which the lymphatic glands are enlarged. We have noticed this, too, in acute cases in adults. As the joint trouble becomes pronounced other symptoms appear and advance with it *pari passu;* occasionally they may even *précédé* any manifestation of articular disturbance (Dr. Spender).[3] Anæmia is generally noticeable early in the case and may become profound: it appears to be due rather to deficiency of hæmoglobin than to destruction of corpuscles. Muscular atrophy is a very marked symptom and one always present. Although as a rule there is a general atrophy of fat and muscle distributed over the whole body and contributing to that cachectic facies so universal in this disease, yet there is a distinct selective agency at work. Some muscles suffer more than others, notably the extensor muscles of the forearms, the abductor indicis, the interossei, and the muscles forming the thenar eminence. Muscles, if affected at all, suffer throughout their entire length, and the atrophy is not limited to the portion near or distal to a joint. The reaction of degeneration is not usually marked. In addition to the muscular atrophies there are various other evidences of trophic and vaso-motorial disturbance. Sudden flushing of the skin of the whole body with copious outburst of sweating is common, while a very profuse cold perspiration of the palms of the hands and fingers is present in almost every case, and may be so copious as literally to drip off. The extremities are usually cold and clammy, and a peculiar livid mottling of the hands, especially over affected joints, is common. The fingers have a great tendency to "go dead," and in five cases we have seen this condition so marked as to merit the title of Raynaud's Disease, there being actual gangrene under the nails. In none of these cases was there any hæmoglobinuria. It was Dr. Spender who first drew attention to the pigmentary changes of the skin in this disease. The changes may consist of minute black freckles, most common on the backs of the forearm, of dark washes of colour under the eyes or across the forehead, or of a general darkening of the complexion. The same writer, too, draws attention to the changes in the cardiac rhythm, and lays great stress on the tachycardia often present. We would wish to point out in addition that it is by no means rare to find an apical systolic bruit (? hæmic) in cases of rheumatoid arthritis in which no history can be obtained of a previous attack of acute rheumatism, while it is quite common to find a booming alteration of the first sound. Pericarditis is occasionally found, but how far it is of a rheumatic and how far of a rheumatoid origin is at present uncertain. Ecchymoses in the skin are quite common. Peripheral neuritis may be present, but there is never any marked disturbance of the sensory nerves. The reflexes, as a rule, are normal.

To sum up, then, the points of special significance in the diagnosis of the disease are: (1) the sex and age of the patient; (2) the soft spindle enlargement of the finger-joints and the swelling of the wrists; together these form the most constant symptom, and in nine cases out of ten the disease can be easily and certainly diagnosed from the hands alone; the accompanying illustration shows excellently the typical deformities, together with the atrophy of the interossei; (3) the cold sweating palms; (4) the affection of the jaws and neck; (5) the cachexia and wasting; and of less importance (6) pigment changes and (7) tachycardia. It is hardly within the scope of this paper to enter into the subject of treatment. At best it is but unsatisfactory. Treatment based on the assumption that the disease is a "rheumatic gout," with consequent deprivation of meat and stimulants, may soon bring the patient to an almost moribund condition. The resisting powers of the tissues must be strengthened to the utmost; rich, nourishing

Digitized by Google

food, alcohol if necessary, cod-liver oil, iron, arsenic, may all prove useful, but, above all, fresh air and sunshine. The wasting and stiffness may be relieved by massage, the stiffness and the pain, which is usually very severe, by hot baths and mild counter-irritants. The prognosis as regards life is fairly good; as regards complete recovery extremely bad. The disease steadily progresses through years of suffering until, the soft structures of the joints being destroyed, either fibrous ankylosis occurs or ordinary osteo-arthritic changes take place, and the disease, having exhausted its pabulum, wears itself out and becomes quiescent. Just as in fibroid phthisis the fibrous tissue is a protective effort of nature to limit the growth of the bacillus, so in the fibrous and osteo-sclerotic ankylosis of joints in rheumatoid arthritis we have a similar defensive action; in neither case, apparently, do the microbes survive in the new-formed tissues.

Turning, then, to the pathology of the disease, as we understand it, we have a disease due to the presence of micro-organisms found in the joint fluids and tissues, and which must until disproved be regarded as specific. How these micro-organisms gain access to the blood is not at present definitely known, but they probably do so through some chronic catarrh of the gastro-intestinal or genito-urinary systems, and such catarrhs are not far to seek. In not a few cases it has been traced, with almost absolute certainty, to the tonsils. Having gained a footing in the circulation the micro-organisms pass freely to all the organs of the body, thus explaining the symmetry of the disorder and why one joint after another should be involved. They now proceed to select a suitable nidus for their growth, and, like all other pathogenic bacteria, they exercise a selective action in their choice which never varies. What governs this selective action is not known; but it appears curious that out of all the sites to which they gain access they should, so far as we at present know, only choose the joints for their habitat. We may note that joint tissues seem specially liable to bacterial infection, *vide* such diseases as pyæmia and gonorrhœa. It is possible that the endocardium and pericardium are also liable to their attacks, as otherwise it is difficult to account for the symptoms referable to those tissues. This point has not been fully elucidated, and, so far, we have no proof one way or another. Probably, also, the micro-organisms grow and propagate in the lesions through which they gain access to the blood, giving rise to those local catarrhs so common during the course of the disease. Owing to the want of post-mortem material these points must be left for future consideration. In the joints we found proof that the micro-organisms grow and propagate, doing so, not only in the synovial membrane, ligaments, &c., but also in the bone marrow and cartilaginous structures. Their presence gives rise to acute inflammatory changes leading to ulceration, erosion, and destruction of the hard as well as of the soft joint tissues. Our specimens are so few that this is only a provisional statement. This process varies in intensity and, usually as the disease progresses a coincident but varying amount of reparative change is seen, which ends in general hardening and thickening of both bones and ligaments. The presence of micro-organisms can be demonstrated in the joint fluid by staining and also in the tissues on section. The joint and heart symptoms are those only which would appear to be due to the direct action of the micro-organisms, and may therefore be regarded as primary or essential, whilst those which are due to their indirect action, through their products, may be regarded as secondary or symptomatic. These latter may vary in every case, not only in intensity, but in nature, yet they would all appear to have a common origin in toxic action.

During their life cycle these, like all other bacteria, give rise to poisonous products, which, being absorbed, pass to the body generally, and, what is of more importance, to the nervous system locally. Here, again, we see either a peculiar selective action on the part of the products acting on or else a peculiar susceptibility of the parts acted on. In this as in other bacterial diseases, we have no definite proof that it is not the micro-organisms themselves which cause the changes in the nerve system, but all argument, analogy, and proof is against it, and, therefore, we may assume that such is the case. As evidences we have the experiments of MM. Vidal and Bezançon,[4] which show that several micro-organisms have the power of producing central nerve degeneration, and although they have been isolated from the blood, yet they have not been found in the central nerve tissues. They therefore appear to act by the elaboration of a soluble poison. Such would appear to be the case in rheumatoid disease. With regard to the toxic action of bacterial poisons on the nervous system, it is of importance to note that nutritional as well as actual organic change may result. Although these nutritional changes are more common in the peripheral nerves, yet toxic agents exhibit such a remarkable selective action, and as we do not as yet know what are the influences which determine such susceptibility it would not be surprising to find similar changes in the central nerve system. From every side evidence is gathering that what may at first be only a depression of the function of a certain centre or group of centres may end, if the irritation be severe, whether it be applied locally in the shape of a toxine or reflexly, in becoming an organic degeneration, not only of that centre or group of centres, but also of the nerve path or paths descending from them. Erb,[5] speaking of progressive muscular dystrophy, says there is a possibility that the disease, starting in a functional disturbance, might in the long run become associated with a coarse lesion of the spinal centres. He says there are many things about such a condition which agree well with this supposition. From this we may conclude that bacterial poisons act on either the peripheral or central nerve systems, producing in one case an organic lesion and in another only a functional depression. Now let us look at the rheumatoid symptoms due to such a condition of the nerve system. The principal and most difficult to explain is undoubtedly the muscular atrophy which occurs not only early in the disease, but is one of the most constant symptoms. The atrophy extends to the whole of a muscle and not only to that part which is in contact with the joint or distal to it, and it follows so closely on the first appearance of the joint troubles as to preclude the possibility of an extension of the inflammation from the joint to the nerves or muscles. Apart from true rheumatoid atrophy we have atrophy occurring as a consequence of a neuritis distinctly secondary in character and only seen in the later stages. Such a condition has been described by Sabourin,[6] Valtat,[7] Strümpell,[8] Duplay and Cazin,[9] and is of less interest than the true rheumatoidal atrophy, and can be easily distinguished from it as it presents all the characters of ordinary muscular atrophy in the reaction of degeneration and alteration in the muscle structure, &c. This is absent in the true form in which the extensors are principally affected, but not exclusively so. The selective character of the atrophy is sufficient proof that the changes cannot be set down to mere disease. How, then, do we account for it? We think it is due to an abnormal condition of the multipolar nerve cells of the anterior cornua.[10] It is reasonable to suppose that, given a soluble poison circulating in the blood, some areas in the central nerve system should be affected, and these all the more especially as they are in all probability predisposed to it by reflex irritation from the joints. That such an irritation does occur has been stated by many observers and has been even said to be sufficient to cause the atrophy itself (Paget, Vulpian,[11] Charcot,[12] and others). It has been argued that, assuming a derangement of the motor cells of the cord determined by the morbid impulses from the joint nerves, the influences from the motor cells will in all probability determine the alterations in the muscle nutrition. In the light of the discovery of the micro-organisms and of recent observations with regard to the action of toxines on the nerve system we may disregard this reflex irritation, except in so far as only to regard it as a predisposing cause. On turning again to the cells themselves we find, according to Ferrier,[13] that the cell-body, with its nucleus

[10] The path of motor innervation is composed of two portions: (*a*) the pyramidal cell with its dendritic processes and centrifugal or axis cylinder process, coursing along the pyramidal tract; and (*b*) the spinal multipolar cell with its processes and axis cylinder process, ending in the muscle fibre. It has been shown by Golgi's (Schäfer: Brain, vol. xvi., p. 147) method of staining that the pyramidal axis cylinders end in an arborescence which merely comes into contact with the spinal cell or interlaces with its dendritic processes, there being no actual continuity.

is primarily concerned in the nutrition of the motor nerve and its correlated muscular fibre, while the dendritic processes serve to convey incitation and functional activity. He also states that lesion of these processes may cause paralysis with all the symptoms of a spinal paralysis, but with no muscular degeneration. If such a condition can exist might we not consider it possible, nay, probable, that by the action of a toxic body the cell's action might by itself be so lowered or held in abeyance that nutritional changes in the muscles would ensue without much disturbance of the conductive faculty of the processes, and also without any degeneration of the muscle beyond wasting? In progressive muscular atrophy we have a slowly progressive lesion of the ganglion cells, and their prolongations in the axis cylinders of the nerve fibres. Might we not, on a modified scale, have such symptoms if, instead of a complete destruction of these cells, we have only a depression of their function? In fact, such a condition must exist, as we cannot otherwise account for the atrophy either by reflex or direct toxic action. The cells' activity must be lowered. In one class of case, of which those mentioned by Dr. Spender[14] may be taken as typical examples, we must assume that the action on the cells has been so great as actually to give rise to a distinct lesion, and this, spreading upwards in the pyramidal tract, has finally come to affect the bulbar nuclei. Folli's[15] discovery of atrophy of the motor cells goes a long way to confirm this theory. What was probably only at first a depression of function due to the changes set up by the rheumatoid toxine had apparently in the long run become actual organic change. With regard to the selective site of the muscular atrophy, we find Dr. Ferrier[16] saying "It is not unreasonable to suppose that the degree of representation, and therefore the trophic strength, of the extensors in the anterior cornua is less than that of the flexors, while such extensors as have the most numerous connexions with the spinal segments would have a greater vital resistance than those whose segments are fewest." From this we may deduct that those muscles with the lowest trophic representation will be those which are first and most affected in any disease which lowers the vitality of the nerves and nerve centres. Duplay and Cazin[17] have suggested that it is due to the anatomical relationship between the nerves which supply the joints and those which supply the affected muscles. This does not explain it all, however, and Dr. Ferrier's explanations seem the more probable and the more easily intelligible, especially if we add that reflex impulses may possibly help in the selection.

It has been proved that certain toxines have the power of producing changes in the vaso-motor system and also in the trophic condition of the skin. It is thus that we account for the local sweatings and pigmentation. We know that normal pigment arises from a particular product of metabolism of the cutis, being formed both in the ordinary epithelial cells and in the connective tissue cells. These connective tissue pigment cells are the regulators of the metabolic process, as they consume the surplus pigment-forming substances. The abnormal pigmentation of rheumatoid arthritis is probably due to a local increase in the formation of the normal pigment consequent upon some abnormal trophic innervation and to a deficient consumption of the surplus by the connective tissue cells. The vaso-motor changes are in all probability due to the centre situated in the cells, in the intermedio-lateral tract being affected in a similar fashion to those in the anterior cornua. One of the chief points of interest is the tachycardia. Bezançon[18] states that tachycardia may in some cases be due to pressure on the vagus, but he suggests that more often it is due to the absorption of certain toxines. He cites the case of the bacillus tuberculosis and also of certain staphylococci, streptococci, &c., of the secondary purulent infection so common in phthisis. Bouchard obtained from tuberculin a substance to which he gave the name ectasine, which had the property of producing dilatation of the vessels. Toxines with similar powers have been obtained from the product of the bacillus pyocyaneus by Charrin and Gley, and from those of the staphylococcus aureus by Arloing. By acting as vaso-dilators these substances would tend to produce tachycardia, since the heart's action becomes more rapid as the peripheral friction diminishes. In other cases the toxines, by giving rise to a neuritis of the vagus, may cause it. Vierordt in a case of phthisis found such a neuritis as was evidenced by a great number of vagus fibres having undergone degeneration and atrophy. With regard to the local sweating, it is probably due to paresis caused by the toxines acting on the sudoriparous and vaso-motor centres of the bulb. Similar action is seen in influenza (Semmola[19]). It has been found by Hunter[20] that in all probability pernicious anæmia is caused by the presence of bacterial poisons, just as it has been found to occur from the presence of cadaveric poisons and analogous ferments. Such being the case, it requires little imagination to conceive that a similar process may occur in rheumatoid arthritis. These bacterial poisons would seem to act by a hæmolytic process which is specially limited in its actions to the portal blood.

DR. BLAXALL'S BACTERIOLOGICAL REPORT.

(From the Laboratories of the British Institute of Preventive Medicine.)

This investigation was undertaken at the request of Dr. Bannatyne of Bath, who stated that he with Dr. Wohlmann had arrived at the conclusion from the clinical aspect of cases suffering from rheumatoid arthritis that the disease was due to a micro-organism; and, further, that by microscopic examination of the synovial fluid from affected joints they had found an organism constant and distinct. This micro-organism they considered to be specific. Synovial fluid from affected joints was sent me from Bath. The fluid was aspirated with antiseptic and aseptic precautions, with such success that out of eighteen cases which have been submitted to me, only twice have I found it contaminated. My first attempts to stain organisms in the synovia and to obtain cultivations from it resulted in failure. I adopted the ordinary methods of bacteriological procedure, staining films of the synovial fluid for a few minutes with aniline dyes and inoculating serum tubes and all ordinary culture media, as well as making plate cultivations of nutrient agar-agar and gelatin, after Koch's method. But I was unable to observe any organisms in the microscopic specimens or to recognise any appearance of growth upon any of the culture media. I then varied the staining methods, leaving the specimens in the dyes for a prolonged time in the cold, applying heat, and using concentrated solutions. By these means organisms could be perceived in the specimens corresponding exactly to those described by Dr. Bannatyne and Dr. Wohlmann, and morphologically identical with those seen in their microscopic specimens. But their recognition was unsatisfactory owing to several causes. In the first place, it was evident that the organisms took up the stains with great difficulty and only by their prolonged action or by the application of heat, but these means resulted in a very dense colouration of the synovial film; secondly, they were decolourised with great ease, for attempts to decolourise the substratum left the organisms unstained. Again, the microbe being very minute, it was exceedingly difficult in heavily stained specimens to discriminate it from débris or from precipitate of the dye used. It was necessary then to find a method by which the organisms should be well stained, should retain the stain and yet allow the synovial film to be sufficiently decolourised, and one that should obviate all precipitation of the dye. I cannot claim to have attained this result, but after many trials I have adopted the following procedure as being most satisfactory. A thin film of synovial fluid drawn out between two cover-glasses is dried over the flame and fixed in the usual way by passing through the flame five or six times, as otherwise the organisms are apt to be washed out. The cover-glass is then immersed in dilute acetic acid for about two minutes, well washed with water and dried again, this second drying being to prevent the cover-glass sinking in the staining fluid. The stain which I have found most useful is aniline methylene blue. The cover-glass is placed specimen-side down on a watch-glassful of the stain and the whole placed in a moist chamber in the dark for from three to five days. It is then washed in gently running water for some hours, rinsed in distilled water, dried, and mounted in the usual way. More expeditious, though not giving such clear and well-defined specimens, are aniline gentian violet and carbolic fuchsine. This latter stain I have found it advantageous to dilute one-third with distilled water. From twelve to thirty-six hours is sufficient for these in a moist chamber. The cover-glasses are washed in running water in

[19] Trans. of the Académie de Médecine, 1891-92.

Digitized by Google

the same way, then well rinsed with 30 per cent. alcohol, washed in distilled water, dried, and mounted. The acetic acid clears the synovial film, and allows the dye to penetrate more readily, the prolonged staining deeply colours the organisms, so that the washing process leaves them well stained, though the film is decolourised, and the moist chamber, by preventing evaporation of the dye, obviates the precipitate. Microscopic examination of the specimens reveals an organism possessing peculiar characteristics. At first sight it appears to be a diplococcus, the two cocci being distinctly stained, but separated by a clear unstained interval about equal in length to the diameter of either stained end. This interval I have never succeeded in staining. But careful observation will show, especially where the substratum is faintly coloured, that the intervening portion is nearly as broad as the diameter of either stained extremity, and that it has parallel contours. I therefore consider the organism to be a bacillus which exhibits very marked polar staining. The average length is 2 μ and the average breadth 0·6 μ, but this latter measurement varies greatly with the intensity of the staining. But the organism, as seen under the microscope, appears much smaller than these measurements would indicate, owing to the limited portions stained. The number of organisms met with in a cover-glass specimen of synovial fluid from a joint affected with rheumatoid arthritis varies greatly. Sometimes the field is crowded with them; at other times they are scattered and hard to find. These differences appear to follow very closely the acuteness or chronicity of the disease. The organisms are generally evenly distributed through the film, showing, however, a tendency to congregate around leucocytes. Their arrangement is always discrete. I have never seen chains or masses formed.

Though the staining methods mentioned above have given me the most satisfactory specimens, yet the organisms can be seen when stained for a much shorter time, especially with gentian violet, methyl violet, or carbolic fuchsine. But it is found that these stains if allowed to evaporate deposit upon the cover-glass a precipitate of dye which so closely resembles the organism that it is by no means easy to recognise them when but few are present in a preparation so obscured. For this reason I have quite discarded heating the stains, because after such a brief staining attempts to remove the precipitate by washing and the use of reagents bring about more or less completely the decolourisation of the organism, whereas after a longer contact with the stain the microbes are coloured more firmly and are less easily decolourised. But there is one exception to this statement in a method which I have devised and found useful. Impressed with the small size of the organism and the minute portion stained, it occurred to me that the protoplasm might take up dyes more readily if it came into contact with them while moist. With this in view I mixed a drop of synovial fluid with a few drops of the stain (aniline methylene blue being best) on a cover-glass and rubbed out with a platinum needle. The cover-glass, with the stain and synovial fluid together, was then dried slowly over a burner and when quite dry fixed by passing several times through the flame, then freely washed with water, dried, and mounted. In this way I obtained very fair results, the greater part of the stain being washed off, leaving the organisms well coloured. For rapid diagnosis this method is very useful. Treated by Gram's method the organism is almost completely decolourised. I have been able also to detect the organisms in the synovial fluid in the hanging-drop specimen, but this is far from easy unless they are present in large numbers. I have now stained and examined the synovial fluid from various joints from eighteen cases affected with rheumatoid arthritis, and in every one have observed the organism which I have described above, but in fluids from distended joints due to other causes, as chronic synovitis, gonorrhœal and tubercular affections, I have entirely failed to find them. (Fig. 1. Synovial fluid, stained gentian violet. × 900.)

Cultivation.—At first all attempts at cultivation, both aerobic and anaerobic, yielded apparently no result; but I imagined that this might be due in part to the small size of the organism—so that if it formed colonies they might be scarcely perceptible, and, judging from the scattered distribution in synovia, that the tendency to a free growth might be small—and in part to a slow development. Keeping these points in view I resolved to try it upon a large scale and in such a manner that any change in the medium might be easily detected. Into litre or half-litre flasks were put 250 c.c. of peptone beef-broth, filtered repeatedly until it presented a perfectly clear and bright appearance. Great care was taken over this to avoid the slightest obscuration. The flasks were sterilised and placed in an incubator kept at blood heat for several days, to prove their sterility and also to be sure that the fluid remained perfectly clear. If these conditions were fulfilled the flasks were carefully opened and a drop or two of synovial fluid from an affected joint allowed to enter. The flasks were then incubated at blood heat. Similar flasks, but *uninoculated*, were also incubated at the same time to serve as controls. I was fortunate enough to attain success with the first experiment. The first point noticed was that for three days the beef-broth remained perfectly clear, pointing strongly to the conclusion that the synovial fluid contained no ordinary organism. But from the fourth day and onward there could be seen floating in the clear fluid very minute particles, and these increasing gave rise to an appearance resembling "gold dust." This effect was enhanced by lightly shaking the flask. Sometimes the growth seems to stop at this "gold dust" stage, but at other times it may become slightly flocculent, recalling to mind the appearance of a commencing growth of tubercle bacilli in glycerine beef-broth. The beef-broth never becomes turbid, but always retains its bright appearance. The control flasks showed no such development. Microscopic examination of such a culture, stained as before, displays the organisms in considerable number; but it can be readily understood, from the delicate nature of the cultures and the imperfections of staining methods, that a too great reliance on stained specimens was not advisable, and that additional evidence would be helpful. Verification was obtained by making hanging-drop specimens, and this is the easiest method of demonstrating the presence of the organism. In the hanging-drop the microbe appears precisely as in the stained specimens, with two bright refractile ends and an intermediate part much less obvious. They may occur in zooglœa masses, or as discreet individuals hugging the edge of the drop. They are non-motile but have a marked oscillatory movement. I have been fortunate enough to see them undergo division in the hanging-drop specimen. The intervening portion lengthens out, the ends appearing to pull against one another energetically, the whole organism oscillating the while uneasily. The middle part lengthens out more and more, so that the organism appears to be almost twice its ordinary length, then suddenly the link snaps and the freed ends fly off in contrary directions and are lost amidst their fellows. This phenomenon helps, I think, to explain some variations in length frequently noticed in stained specimens from cultures. In these, some bacilli will be seen very short, the stained ends quite close together, with a minute unstained connecting link, very suggestive of a diplococcus. These I take to be quite young organisms. Some, however, are much longer, attaining a length of 3μ or possibly 4μ, the stained ends widely separated, and a clear, unstained sheath faintly visible with the highest powers. These I imagine to be the older forms soon about to divide. In these older forms, too, the staining is sometimes somewhat different. Instead of the stained portion being more or less spherical at the ends of the organism the coloured part is in the form of a conical cap, the base towards the centre of the bacillus, and spreading faintly down the edges of the sheath. These forms show best the claim of the organism to be considered a bacillus. It will be obvious, however, that it is very difficult to bring out these subtle differences in a photograph, and, indeed, the limited staining of the organism and its minuteness render the production of good photographs by no means easy. (Figs. 2 and 3. Fig. 2 shows a beef-broth culture, stained fuschin. × 1200.) If beef-broth cultures are inoculated on tubes of sloping nutrient agar-agar and incubated at blood heat, growth takes place in about three days and in a very characteristic manner. This growth is exceedingly delicate. It appears no more than as a fine transparent film, which under a lens can be seen to consist of minute colonies no larger than a pin point and perfectly transparent. To the naked eye it bears a very close resemblance to condensation water, though control tubes and the obvious tests show that this is not the case. It grows also on Löffler's serum, but here the growth is even more difficult to recognise owing perhaps to the opalescence of the medium. It occurs as minute points, least difficult to observe at the lower part of the tube, where the condensation water has washed off the cholesterin. Stained cover-glass specimens and hanging-drop specimens made from such cultures reveal

Digitized by Google

an organism identical morphologically with that described as present in the beef-broth cultures and synovial fluid. I have also grown the organism in milk, where it appears to flourish, but without causing curdling or precipitation of the casein. On nutrient gelatin, however, at 22° C. I have never succeeded in getting a growth, and in liquid gelatin, incubated at 37° C., there is no visible growth. Examination of the blood in cases affected with rheumatoid arthritis has also afforded me positive results of the presence of the organism. I have examined the blood taken near to an affected joint and also that from a distance, and in both have been able to detect the organism in microscopic specimens. Out of five specimens of blood submitted to me I have been successful in three, and these were the most severe cases. But further proof of the presence of the organism in the blood is the fact that twice I have been able to obtain cultures from it. The method was the same as previously described. The blood was inoculated into flasks of clear sterilised beef-broth and incubated at blood-heat temperature. Sub-cultures were also made from these flasks on to agar-agar and blood serum. The organism found was identical in every respect with that which grew from the synovial fluid and with that which was observed in the stained specimens. Some animal experiments have been made for which I am indebted to the Council of the Royal College of Surgeons of England and to Dr. G. Sims Woodhead. Two cubic centimetres of a beef-broth culture were injected subcutaneously into mice, guinea-pigs, and rabbits, but without a fatal result. There is some reason to think, however, that the cultures set up a disease in rabbits which affected the joints, but further experiments are necessary to arrive at the truth with regard to this matter.

As far as I am aware, only one organism has been previously associated with rheumatoid arthritis which it is necessary to discuss. This was described by Schüller.[21] He writes of a bacillus 2·6 μ long and 0·75–0·995 μ broad which exhibits polar staining. It is easily coloured by ordinary stains, especially carbolic fuchsin, but very easily decolourised. It is noteworthy that Schüller thinks it incumbent on him to point out the distinction between his organism and tubercle bacilli. It grows readily upon gelatin at 25° C. In 2–3–6 days small white grains or knobs appear. The gelatin is liquefied, and eventually the organism grows to such an extent that the whole mass becomes an opaque white. On agar-agar it grows as greyish-white flecks or films. It is obvious that the organism described by Schüller differs markedly from the one under discussion; in fact, the only points of resemblance are the polar staining and the easy decolourisation. It therefore appears to me to be indisputable that the organism of Schüller is not that which was discovered by Dr. Bannatyne and Dr. Wohlmann.

To sum up. 1. In the synovial fluid of eighteen cases of rheumatoid arthritis an organism has been demonstrated which is constant in its characteristics. 2. The organism is a minute bacillus exhibiting marked polar staining. It is difficult to stain and easily decolourised. 3. The organism can be grown in culture media and presents striking characteristics. In beef broth it gives the appearance of gold dust and on agar-agar and serum its growth is almost invisible. It does not grow on nutrient gelatin at ordinary temperature. 4. It is present in the blood in severe cases. 5. It has not been found in the synovial fluid from distended joints due to other causes. It should be added that it has been impossible to examine sections of the synovial membrane owing to the want of pathological specimens. In conclusion, I should like to record my thanks to Mr. Barnard for the care and skill he has expended on the photographs.

MEDICO-PSYCHOLOGICAL ASSOCIATION. — The spring meeting of the South-Western Division was held at Bailbrook House, Bath, on the 14th inst., the President being in the chair. There was a large attendance of members and several important resolutions were passed. The report of the Committee on Criminal Responsibility was ordered to lie on the table. The discussion on the "nursing staff" was taken part in by several members. Dr. Stewart contributed a useful note on Section 38 of the Lunacy Act, 1890. The members afterwards dined together at the Grand Pump Room Hotel.

COLOUR VISION.[1]

BY W. G. LAWS, M.B. EDIN., F.R.C.S. ENG.,
SURGEON TO THE NOTTINGHAM AND MIDLAND EYE INFIRMARY.

THE speaker pointed out that the subject lay in the debatable region between mental states and physical processes, where so many interesting problems remained unsolved. The eye was the end organ which brought us into direct relation with the ether, that ultimate form of matter as to which it became possible to doubt whether it was material at all, and which probably entered closely into the processes of thought itself. Before speaking of the theories of colour vision it might be asked what was there in colour vision that so many scientific minds had felt required explanation. It would be noticed that every theory contained the same fundamental idea that there must be a certain number of colours, varying with different observers, but always few, which were to be regarded as pure or simple colours, all others being considered as compounds or mixtures of these. On looking at the perfectly continuous series of colours which we see in the spectrum there seemed to be no obvious physical reason for this distinction. It was, indeed, a psychological rather than a physical one. We had an innate disinclination to conceive of an infinite number of different causes for the infinite number of different sensations of which we were conscious; it was a principle deeply rooted in our reason, expressed long ago by William of Occam, whose famous Razor, "*Entia non sunt multiplicanda*," was employed by us nowadays as constantly in the solution of physical problems as it was by the Invincible Doctor in the division of the sophistries of Rationalism. Mr. Laws hoped to show, however, in relation to one at least of the theories that it was possible to cut too close with it. Many theories of colour vision had been proposed during the last 200 years, some of them interesting and original, but two only had gained any general acceptance and to these the discussion would be confined. He then described the theory of Young as it was published in 1801, its modification by Helmholtz more than half a century later, with his proof of the mathematical possibility of reducing all our colour sensations to three. Hering's theory was next described, mainly in extracts from his original papers, Mr. Laws considering that none of the published accounts of it in this country did justice to the simple conception, the logical development, and lucid expression of the theory as stated by Hering himself. What we might fairly demand of a theory of colour vision was that it should give a reasonable explanation of our everyday experience with regard to our sensations, and also should furnish us with a trustworthy guide when the conditions were modified by pathological processes. As it was impossible for him to discuss all the phenomena in the light of these theories he would make the appeal only to an experiment made for us by nature, namely, the condition of congenital colour-blindness. Of this Mr. Laws considered that practically only one type existed, admirably described in Dr. Pole's account of his own case; that other types had been described was due to the attempt to make the facts of observation fit with an erroneous theory; the rare cases of monocular colour-blindness were quoted as highly conclusive on this point; finally, the verification was at the hand of each one in the colour-blind zone of his own retina. He summed up the evidence from colour-blindness as showing that whenever there is a diminution of the number of our colour-perceptions it is not *one* that disappears, but always a *pair* of complementary colours. Here was the reason that the trichromic theory of Young failed—it was not in harmony with the essentially paired character of our colour sensations. Further examples of this character were given in the phenomena of successive and simultaneous contrast, and it was pointed out that we have only to look at a colour in order to call up the sensation of another as definite and (under proper conditions) as brilliant as the former, and having the constant psychical character that it is the greatest possible contrast to the former that our minds can conceive. The physical relationship of the two was such that if the spectrum be divided into two halves, and the more refrangible be superposed on the less refrangible half, then colour by colour and shade by shade the one will neutralise the other and a colourless band result. The

[1] Abstract of a paper read before the Nottingham Medico-Chirurgical Society on April 15th, 1896.

Digitized by Google

dividing line between the two halves corresponds to the neutral point of the spectrum of the colour-blind, and thus the same relation holds for their spectrum as for ours. This very remarkable relationship had, he thought, had less importance attached to it than it deserved. The three pairs of antagonistic chemical processes of Hering seemed to him but crudely to account for the facts. Might there not be a deeper cause for it? Much light had been thrown of late years on the relations of light and electricity, originally by Clerk Maxwell's mathematical development of the relations of certain physical constants into an electromagnetic theory of light, and, perhaps more strikingly, by Hertz's demonstration of the possibility of producing electromagnetic waves which had all the essential characters of those of light. We know as little of the real nature of electricity as of that of the ether; perhaps, indeed, they were one and the same thing; but one of the most characteristic properties of the former was its power of producing a condition of polarity, or the separation of equal and opposite energies, in matter under its influence. Might not this furnish a clue to the intimate nature of the action of light on the retina and so lead to a completer theory of colour vision than we yet possess?

LITHOTRITY IN CASES OF STONE: SIMPLE AND COMPLICATED.

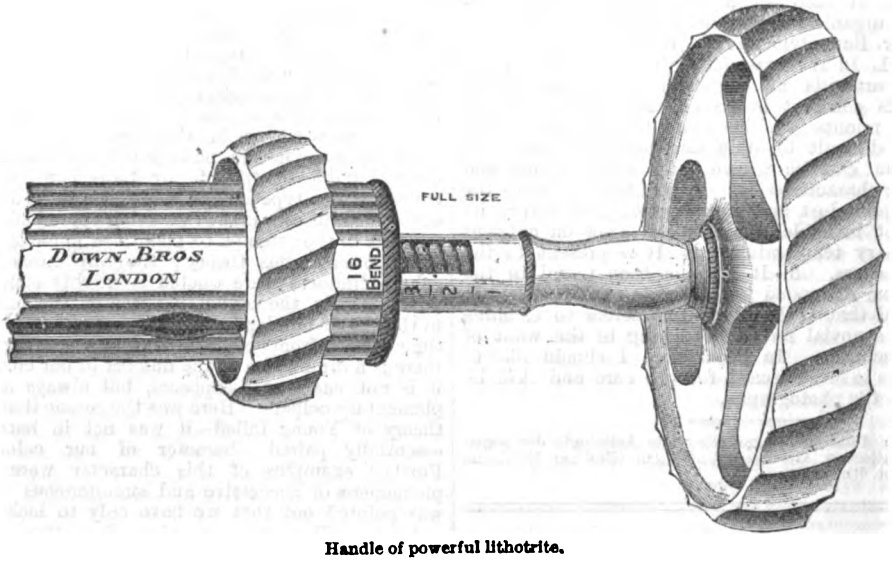
BY HERBERT MILTON, M.R.C.S. ENG.,
PRINCIPAL MEDICAL OFFICER, KASR-EL-AINI HOSPITAL, CAIRO.

(Continued from page 1066.)

THE result of Bigelow's operation for large stones has been excellent, fifteen cases over two ounces without a death, but at the same time it must be admitted that the execution of such operations is not facile. First as to the instruments required. The lithotrite to deal with large stones must be very powerful and at the same time such that the power can be discriminately and delicately applied. It must also be so constructed as to cause the least possible toil to the operator—a matter of great consideration in an operation lasting between one and two hours. I have always employed a modified Thompson's lithotrite. The modifications have been carried out for me by Messrs. Down Brothers, who have kindly expended great time and trouble in the work. They have produced for me instruments of the most excellent make and finish. I have seen and used lithotrites by many makers, English, American, German, French, and Italian, but have never come across any to compare with the ones they have lately made for me. The instruments I use for large stones are two. The first has a gape of two and a half inches; it measures fourteen English in the shaft and fifteen and a half at the shoulder. It is fully fenestrated and has a comparatively short beak. It has two modifications in the handle (Fig. 6). The wheel is much larger than usual; its diameter is two and a half inches and is made of aluminium for lightness. This increased size of the wheel adds very considerably to the pressure which can be exerted on the stone and also greatly increases the delicacy with which the pressure can be applied. The button which is generally employed to bring the screw action into play is replaced by a ring surrounding the handle. This ring runs very easily and it can be pressed on by the forefinger or thumb without altering the grasp on the handle, which is made a little longer than usual. I have never yet met the stone which this instrument has not been powerful enough to crush and I doubt very much whether such stones ever occur. I have had stones, however, too large to be seized in its grasp. I have therefore had made another lithotrite exactly similar in construction except that its gape (Fig. 7) is five inches—a gape sufficient for any stone ever yet met with. It was with this instrument that I crushed the stone of twelve ounces.

The evacuating tubes for operations on large stones should be straight and as large as possible. Egyptian patients have, I think, exceptionally large urethras, and I have frequently been able to introduce a No. 22 English, and I usually work with a No. 18 or 20. Of course, no force must be used in introducing a tube, but the largest should be used that can be introduced without violence. Secondly, as to the operator. There is no question that in order to crush a large stone well the operator must be in thorough condition and in constant practice, or, to use a sporting term, be in "training." During the first twenty minutes of a long crushing most men can maintain the necessary delicacy of manipulation combined with the exercise of considerable force; but when it comes to working at the same strain for a second, third, fourth, or even fifth, sixth, or seventh period condition begins to tell. The force required to be exerted is often the full power of a strong wrist and arm even when using the powerful instruments I have described, and this force has to be exerted with great discrimination and great patience. Nothing, I think, can be sounder than the advice given by most experienced lithotritists to beginners not to crush big stones. I would, however, modify this advice to beginners thus: not to crush big stones except through a perineal incision. Given powerful instruments and an experienced operator the difficulties likely to be met with in crushing big stones are two. The first difficulty is in the seizure of the stone. This difficulty may arise from one of two causes—the size of the stone or the contraction on it of the bladder wall; very frequently the two are co-existent. With ordinary lithotrites the mere size of the stone may render it impossible to bring the screw power into action. Reference has been made in THE LANCET to a lithotrite built for an Indian surgeon to cope with such enormous stones. He had found on one occasion when grasping a

FIG. 6.

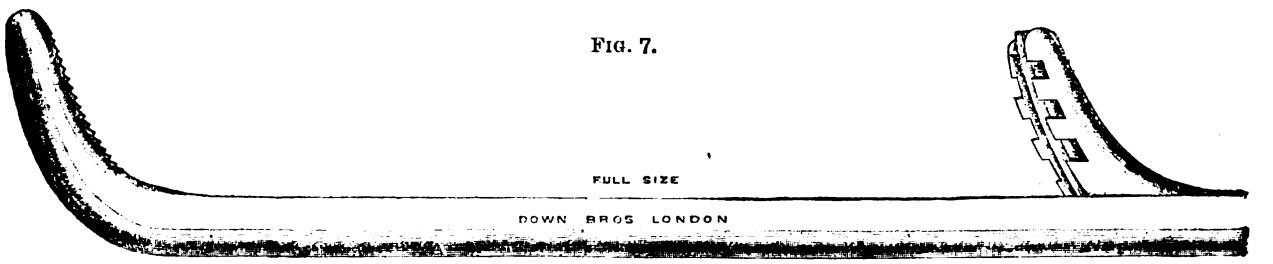


Handle of powerful lithotrite.

Digitized by Google

large stone that the whole of the male screw projected beyond the handle of the lithotrite and that in consequence the screw action was completely out of gear. His remedy, devised on the spur of the moment, was excellent and was as forcible in execution as it was ancient in conception. He hammered the projecting extremity of the male blade until, after suffering considerable damage, it returned within the limits of the screw action. To meet an emergency the remedy was excellent, and to judge from the description the operator exhibited a perseverance which fell but little short of that of the French surgeon who early in this century only abandoned the attempt to fracture a stone by the same method after delivering a thousand blows. To construct a new instrument, however, to carry out this treatment was but to return to the percuteur of Baron Heurteloup, which was entirely superseded half a century ago by Weiss's screw action. The new instrument apparently embodies a percuteur as an addition to the screw action; it would seem to be much simpler to extend the screw, as has been done in my larger lithotrite, to the required dimensions. With this instrument any stone can be seized. The largest stone in my collection, weighing 34½ oz., comes easily within its grasp. It is hardly likely to come in contact with a larger one. The other cause of difficulty in seizing a large stone, the contraction on it of the bladder walls, is much more important. In my earlier operations I have on various occasions abandoned a lithotrity on this account. I have found that large stones are very frequently accompanied by extreme irritability of the bladder and partly from this cause and partly from the stone in some cases being large enough to occupy the whole bladder cavity the muscular walls are so contracted on it as to offer a very great resistance to the insinuation of the blades of the lithotrite. The force required for this insinuation is often such as to raise great apprehension in the mind of the operator as to with a very large one I prefer to introduce, if possible, from 400 to 500 grammes. If necessary I maintain the pressure of 75 centimetres for five minutes, and then if the resistance is not yet overcome I raise the recipient one metre above the bladder level. This is nearly always sufficient after from three to five minutes, but in some rare cases I have had to increase the pressure to one metre and a quarter, which I consider, when all due precautions are taken, to be within the limits of safety, and at this level I have never met with failure. The presence of this considerable quantity of water in the bladder renders the seizure of the stone not only possible but with ordinary skill and patience easy. It must be remembered, also, that a stone has a smallest as well as a largest diameter. It often happens that a stone which when first seized is too big for the gape of the instrument may when grasped at another point come easily within the range of the screw action. It has been proposed by some operators to deal with such stones by gradually picking off fragments with the lithotrite until the mass is sufficiently diminished to allow of its being seized. This process is, however, of necessity slow, and I prefer to use an instrument with a sufficiently large gape. The second difficulty arises in the crushing. The resistance of the stone to the action of the instrument may be very great. It is due much more to the hardness of the stone than to its size, very large stones being frequently phosphatic in nature, soft, and friable. The most difficult stones to crack that I have come across have been between two or three ounces in weight. The oxalate of lime stone is, I think, the hardest of all, but I have met with stones composed chiefly of urates with a slight admixture of phosphates, which have been almost if not quite as resistant. For such stones the lithotrite must be strong and heavy and absolutely trustworthy, but with an instrument such as I use and have described above every stone may be crushed. They are not, however, to be crushed by simple force. The amount

FIG. 7.



Gape of powerful lithotrite.

the possible effects on the walls of the bladder. The danger of any serious injury is, however, in reality very slight, the bladder walls being often much thickened, and being in all cases very resistant to, and probably proof against, all steady movements of a blunt instrument within anything like reasonable limits. In such cases the distension of the bladder with fluid may be a great assistance, though it is often difficult of execution and, unless properly carried out, not devoid of danger.

Bladders have been ruptured by forcible injections during lithotrity and such cases have been recorded. In the overcoming of bladder resistance, however, time as well as force is an important element, and a long-continued slight pressure is as effectual as it is free from danger. In cases where there is considerable resistance and where distension is necessary I attach great importance to the use of continuous hydrostatic pressure. I pass into the bladder the largest size evacuating catheter that will easily enter, and after emptying and washing out the bladder I insert into the catheter the nozzle of an indiarubber tube one metre in length, terminating in a glass recipient, graduated in grammes and holding 1 kilo of boracic acid solution. The bore of the nozzle is 1 millimetre in diameter, so that the current can only enter the bladder very slowly, and every precaution is used to prevent the introduction of any large quantity of air. The recipient is now elevated 50 or 75 centimetres (20 to 30 inches) above the bladder level. In most cases 50 grammes or so of fluid enter the bladder at once, and the flow then either ceases or owing to the rejection by the bladder of the fluid introduced the level in the recipient rises again. Usually after a minute or two, and after various oscillations of level, 200 or 300 grammes of fluid, equal to about 8 to 12 ounces, enter the bladder. For an ordinary large stone this quantity is sufficient, but where dealing of pressure exerted by the jaws of the lithotrite is, of course, the principal factor, but, as in the dilatation of the bladder so here also, time has a very important influence. The experienced operator generally knows when he has before him a really hard stone. It has probably existed for some time and has grown very slowly. The urine is generally acid and contains little or no mucus or pus; there is, in fact, no considerable cystitis. The sound gives out a ringing note and the stone usually moves freely about in the bladder. In the presence of such a case let him choose his strongest lithotrite. Having seized his stone, which is often a matter of difficulty, as many very hard stones are round and smooth, he will probably find that the male blade is sharply arrested with something like two inches of screw projecting from the handle. Directly he applies the screw force he will experience an abrupt resistance which all the strain he can or dare apply is unable to overcome. Let him wait half a minute and then put on an extra half or quarter turn; if necessary let him repeat this wait and this extra pressure two or even three times, and the reward of his patience will almost certainly be the same as has always happened to myself. During one of these periods of waiting a sharp explosive crack will be heard and the difficulty of the case be over. A third difficulty in crushing a large stone arises from the amount of débris. I am convinced that in dealing with small stones the method adopted by Guyon is most excellent. He generally submits the stone to a very prolonged crushing before removing the lithotrite, occupying as much as twenty minutes in reducing the stone to the smallest possible fragments, and in many cases he continues the crushing until he has satisfied himself that all the fragments are small enough to pass through the evacuator. In this way the operation is completed with one or at most two introductions each of the lithotrite and of the evacuator,

Digitized by Google

and much bruising and injury is spared to the urethra and prostate. In dealing with large stones I consider, however, that it is better to evacuate fragments frequently, and in such cases I stop crushing so soon as I feel my lithotrite impeded by the collection of many fragments and evacuate. In the early part of a prolonged operation I may remove my lithotrite after fifteen or sixteen crushes and evacuate, and I generally find that the procedure is thereby greatly facilitated. In removing, for instance, the twelve-ounce stone I must have introduced the evacuator at least six times before removing two ounces of débris; on the other hand, five or six evacuations sufficed to remove the other ten. I would give, then, a general rule as follows. When dealing with small stones endeavour to complete the fragmentation without removing the lithotrite, but in the case of large stones evacuate as soon as there is so much débris as to interfere with the free use of the lithotrite.

It will be gathered from the above remarks with regard to the suitability of Bigelow's operation as a treatment for large stones, that although the results obtainable may be excellent considerable practice is necessary before such results can be obtained. For the surgeon who only occasionally meets with stone cases I consider that there are other methods of operation more likely to meet with success, and of these other methods I should certainly give preference to that to which I have referred under the name of perineal lithotrity. There are various methods of performing this operation, but they all may be classified under three heads: (1) an incision is made into the urethra from the perineum and a strong lithotrite passed from this incision through the remainder of the urethra into the bladder; (2) an incision is made into the urethra from the perineum, the remainder of the urethra is stretched by some dilating instrument, and passage into the bladder thus given to a large stone crusher; and (3) an incision is made from the perineum into the bladder as in any one of the various classical operations for perineal lithotomy, and through this wound a stone crusher is introduced into the bladder. The first method has been recently practised and advocated by Keith.[1] He gives an excellent description of the operation and refers to very good results. I fail to see, however, what is gained by the procedure. The method is just as difficult as urethral lithotrity, if not more so, and it in no way increases the scope of the latter operation, which has been shown to be capable of removing stones much larger than any removed by Keith. I would limit its application to cases in which it is impossible to pass the lithotrite down the penile portion of the urethra. The second method was strongly advocated by Dolbeau, but in his hands and in those of other surgeons the results yielded have not been favourable. The method is very fully described in the French Medical Encyclopædias. The third method is the one I have chiefly practised myself and which I consider to be the best operation for large stones in the hands of the general surgeon. The method is referred to in most textbooks on surgery and is most generally condemned. As therein described, the perineal incision has been single, double, or multiple. Many forms of crushing instruments have been devised and unfortunately used. They have generally been most ingenious and more cumbersome. I have myself employed but one form for this operation, making a left lateral incision into the bladder and using a simple straight strong pair of forceps as a crusher (Fig. 8).

I will describe one of my operations, which will serve as a type for them all. The patient was an Egyptian fellah, male, aged fifty-four years, suffering from a large vesical calculus. The bladder was washed out with boracic acid solution and a laterally grooved staff introduced. The usual incision for lateral lithotomy was made into the bladder, the skin being freely divided, the prostate and neck of the bladder but slightly. The forefinger of the left hand was then inserted into the wound as the knife was withdrawn, and guided by the staff was insinuated in the bladder, dilating the wound in its progress. This method is in opposition to the directions usually given in text-books; I have, however, uniformly adopted it in all lateral lithotomies, of which, as shown in Table I.,[2] I have performed twenty-eight without a single death. My reasons for advocating this method are: (1) the diminution of the risk of hæmorrhage; (2) the exact limit thereby given to the wound in the neck of the bladder; and (3) the facility of the procedure. It must be observed, however, that all forefingers are not suitable for this purpose and that it is more difficult of execution and less advisable in the case of small children. Care must also be taken to insinuate the finger and not to use any violence to the neck of the bladder. In perineal lithotrity I have found this method particularly useful, as my crushing forceps coincide in diameter with my forefinger, and where the latter has been introduced they can easily follow. Having passed my finger fully into the bladder the staff was first withdrawn and then my finger. A careful examination of the incision having shown that there was no considerable hæmorrhage the crushing forceps, carefully oiled, were introduced through the wound on to the stone. Each handle of the forceps being held in one hand, the jaws were carefully opened, and, at the same time, their extremities were kept in careful apposition to the stone. There was, as is usually the case, some resistance to the opening of the forceps due to the stone being driven down to the neck of the bladder by muscular contraction. Graduated pressure on the forceps was sufficient to push the stone upwards and to thus free the jaws of the forceps from the constriction. The jaws, still in apposition with the stone, were then cautiously and easily opened until a large portion of the circumference of the stone was included in their grasp. The stone thus held was moved about in all directions and twisted through a quarter circle to ensure that no bladder wall was included. With ordinary care such an accident is almost impossible, and the difference in sensation as conducted by the forceps gives immediate and easily recognisable evidence should it occur. An endeavour was then made to crush the stone with the hand power only; but as this failed the screw action was applied with immediate success, the stone breaking with an audible report. One or two slight movements of the forceps sufficed to free the jaws of the crusher from fragments. The bladder was then carefully sounded with the closed forceps and a large fragment fixed upon. The forceps were again opened in the same cautious manner as before and this fragment crushed. This manœuvre was repeated three or four times until the amount of débris was such as to impede the crusher. This was then removed from the bladder, great care being taken to free its jaws from all fragments which might injure the wound during its extraction. These fragments might be detached either by movements of the forceps or with a thick

blunt probe. The crusher being removed, the finger, carefully oiled, was introduced into the bladder, partly in order to recognise the existence of fragments small enough and partly to place them in the most favourable position for extraction. A very small pair of lithotomy forceps was then introduced into the bladder and fragment after fragment removed. Great care was taken to attempt the removal of no fragments so large as to be difficult of passage. A repetition of these manœuvres of crushing and removal was sufficient to eventually entirely evacuate from the bladder a stone weighing 102 grammes or nearly 4 ounces. The bladder was then carefully washed out with a strong stream of water through the largest sized evacuating catheter. The whole of its walls were thoroughly explored by the finger and every fragment of stone removed. The operation lasted nearly thirty-five minutes. The patient left the hospital completely cured three weeks later. I have performed this operation on twenty occasions for large stones; of these, five weighed between 2 and 3 ounces, seven between 3 and 4 ounces, four between 4 and 6 ounces, and four between 6 and 8 ounces. Every one of these twenty operations was successful. The operation, therefore, has given me the most successful results. I consider it to be much easier of execution in such cases than ordinary lithotrity and to be much safer than suprapubic or other form of lithotomy. I would recommend it to the general operator as the best method of coping with large stones. The reproach has been made to this operation that it is likely to be followed by a perineal fistula. In my own practice this has so far not occurred, and if great care be taken to remove all fragments there is but little chance of its occurrence. I would at the same time recommend great attention to the following points:—(1) The crusher should be a simple, powerful straight forceps, a little less in diameter when closed than the operator's forefinger, and should have a simple screw attachment; (2) the wound into the bladder should be only of such size as to admit the forefinger; (3) everything introduced into the bladder should be freely lubricated; (4) the extremities of the jaws of the forceps should be kept touching the fragment about to be seized, and every care taken to avoid seizure of the mucous membrane; (5) the greatest gentleness should be exercised in all movements; (6) no fragments should be removed by means of the crusher; (7) no attempt should be made to remove any fragments except such as can pass with complete ease; (8) the forefinger should be continually used to explore the condition of the bladder and the position of the fragments; (9) the greatest care should be taken to leave no fragments behind; and (10) complete cleanliness is absolutely essential.

I formulate the above axioms only after great consideration, inasmuch as they differ somewhat from the teaching of Reginald Harrison, who has done more than anyone to establish perineal lithotrity. He first brought his method before the profession in 1888, and up to May, 1895, had performed 150 operations all successfully.[2] He prefers to make an incision into the urethra only, and to introduce through this opening a crushing forceps into the bladder, the crusher having about the diameter of a forefinger. My experience has been that a forefinger cannot be introduced without laceration of the tissues about the neck of the bladder, and I prefer to determine the direction of this laceration downwards and outwards by a small incision rather than to leave it to chance. He utilises also the crusher to remove fragments, supplementing this instrument by washing out the bladder with an evacuating syringe. For myself I am convinced that the removal of fragments by an instrument which when closed equals in size the original opening cannot but be attended with laceration or bruising of that opening, and I think greater safety is obtained by using the crusher for crushing only and by removing fragments with a fine pair of forceps or with a spoon. I consider also that the difficulty which certainly exists in this operation of entirely removing every fragment necessitates a thorough digital exploration of the bladder. This cannot, I think, be effectually done through an incision into the urethra only. In principle, however, the operation recommended by Harrison in 1888 is identical with that which I have, following his indications, found so useful. His results also have been more favourable than mine, he having performed fifteen cases without a death, whereas I out of twenty-seven have lost one. With regard, therefore, to the treatment of the first complication of cases of stone, I am of opinion that the results obtainable by lithotrity are better than those which have been obtained by any other form of operation on stones exceptional for their size and hardness. I consider that practically every bladder stone uncomplicated, except with regard to its size and its hardness, can be removed by one of the two forms of lithotrity above described. The proportion of such cases suitable for the one operation or the other will depend on the experience of the operator. Bigelow's operation I consider to be the more brilliant, perineal lithotrity the more generally useful. The indication for the latter operation increases with the size of the stone and diminishes with the experience of the operator.

The next complications to which I have to refer are those arising from the position of the stone. Leaving out of consideration stones entirely outside the bladder cavity, the abnormal positions that I have had to deal with are four: (1) the stone has been partly in the bladder and partly in the ureter; (2) the stone has been lodged entirely or partly in a diverticulum of the bladder; (3) the stone has been lodged in a deep pouch behind the prostate; and (4) the stone has been partly in the bladder and partly in the urethra.

1. *Where the stone has been partly in the bladder and partly in the ureter.*—I have met with and diagnosed during operation three cases of this somewhat rare condition. In all of them there was in addition a stone entirely in the bladder cavity, and it was only on the removal of the bladder stone that the one impacted in the ureter was detected. Quite lately I have met with a case in which the only stone present was impacted at the opening of the right ureter. This case was diagnosed before operation, and supra-pubic cystotomy was performed for the removal of the stone. The first case I met with is worth recording. The patient was a healthy Egyptian fellah aged about fifty years. A largish stone had been diagnosed and I performed lithotrity. After removing some 60 grammes of débris, and after the evacuator had long ceased to remove any fragments, I could still feel and hear a stone on sounding. Repeated attempts to seize this with the lithotrite failed entirely. The stone, as felt by the sound, always occupied the same position on the right side of the base of the bladder. My suspicions being aroused I examined per rectum and felt a distinct, immovable, hard mass which I could balance between my finger and the sound. The position corresponded exactly to the point of entry of the right ureter into the bladder and the diagnosis was thus established. After much consideration I decided to attempt its removal and proceeded to open the bladder by a perineal incision. A supra-pubic opening would probably have been wiser, but the stone as felt per rectum seemed quite close at hand to the perineum. A finger introduced into the bladder easily recognised the stone, which after some difficulty I managed to seize with a lithotomy forceps. All traction, however, failed to move it. I proceeded to incise the opening of the ureter into the bladder, passing a long knife with a rounded cutting extremity along my forefinger on to the stone. After much difficulty I sufficiently liberated the stone to allow of its removal. The stone was an inch and two lines in length and nearly two inches in circumference. There was a very marked neck or construction corresponding to the orifice of the ureter; the part beyond this, about a sixth of the whole stone, had projected into the bladder; the other five-sixths had been retained in the ureter. The result of this operation was unsatisfactory, the patient dying some twenty days after the operation. Post mortem there were found very marked old kidney degenerations and a sub-peritoneal abscess around the right ureteral opening. This case is mentioned in the tables under the heading "Other." In my second case the diagnosis was made in exactly the same way as in the one above described. I decided, however, that if I could not seize the stone with my lithotrite I would let it be. After many fruitless essays I at last grasped it by pushing the stone up to the lithotrite with a finger introduced into the rectum. The stone remained at first immovable from its position, and during an extra strong effort the grasp of the lithotrite slipped. I was able, however, to grasp the stone again and after several trials succeeded in drawing it out of the ureter. Its subsequent crushing presented no difficulty and the case recovered perfectly. In my third case the diagnosis, treatment, and result were the same as in No. 2. In this case,

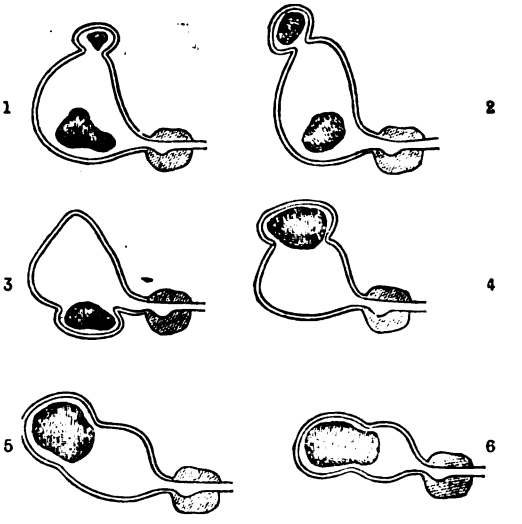
[2] Vide reprint of a lecture on Some Points in the Practice of Lithotrity and Litholapaxy, John Bale and Sons, London, 1895.

Digitized by Google

however, I kept the débris of the two stones quite separate. The bladder stone weighed 19 grammes and consisted of urates and oxalates; the ureter stone weighed 3 grammes and consisted of oxalates, urates, and carbonates. This condition is more common than is usually recognised, many cases having perhaps been diagnosed as stone in a diverticulum of the bladder. A most interesting case is recorded by E. H. Fenwick[4] of a double stone, one part of which is described as being in the bladder and the other in a diverticulum outside the base and back of the bladder. The very difficult operation for its removal was successful, and no more exact determination was therefore possible, but the condition so closely resembles that of my first case, in which the diagnosis was unfortunately confirmed by a necropsy, that I strongly suspect that in Fenwick's case also the stone was lodged in the dilated ureter. The same remark applies to a case reported by McArdle,[5] to one reported by T. V. Jackson to the Pathological Society of London, and to one at least of the cases described by Bruce Clarke in his paper on Latent Calculi.[6] Thomas Smith records a case.[7] Buckston Browne records a probable and Pitts a certain case in the Transactions of the Clinical Society of London, 1890, p. 89. At the same meeting Freyer described a stone partly in the bladder and partly in the ureter which was successfully removed at the second operation. Buckston Browne refers to another case in the Transactions of the Clinical Society of London, 1889, p. 36. The above records show that the condition is sufficiently frequent to be of a real importance, and I consider that in all operations for bladder stone the orifices of the two ureters should be carefully examined. Further, I think it of special importance to thoroughly examine this region in cases in which stone has been suspected and not found. The examination, to be effectual, must be bimanual. The forefinger of the left hand should be introduced into the rectum and should thoroughly explore the base of the bladder. The same region should at the same time be explored by a sound introduced into the bladder per urethram. Frequently this examination cannot be satisfactorily carried out except under chloroform, but if properly performed the presence of a stone partly in the ureter may be rendered either certain or very probable. Having detected a stone in this condition how should it be treated? In my opinion a through trial should be given to lithotrity. A small, light lithotrite should be used, the position of the protruding part of the stone carefully determined, and an attempt (to be repeated many times if necessary) made to seize it. The stone having been grasped by the lithotrite, half a turn of the screw should be given to tighten the grip and attempts be made to pull the stone into the general bladder cavity. Great assistance, both in seizing and dislodging the stone, may be given by a finger in the rectum. Should it be possible to grasp the stone but not to dislodge it I should not attempt to crush it *in situ*, there being too great a risk of crushing surrounding tissue at the same time. Having given a fair trial to lithotrity, and having failed, I should at once perform suprapubic cystotomy, enlarge the orifice of the ureter by careful dilatation or by several small incisions, and, if necessary, break up the stone with a small pair of necrosis forceps. The result of my operations for this condition has not been good. I have operated in all four times (once since commencing this paper), with a mortality of 2, or 50 per cent. The two successful cases were lithotrities. In the two fatal cases lithotrity failed, in the one I did lateral and in the other supra-pubic cystotomy.

2. *Where the stone has been lodged in a diverticulum of the bladder.*—I have met with six cases in which I have been able to diagnose the position of the stone in a sac communicating by a large or small opening with the bladder cavity. I have met with two others in which the condition, though certain, had not yet reached an advanced stage, and several cases in which the stone, though not encysted, always occupied a special portion of the general cavity. Of the six cases of complete sacculation (Fig. 9) Nos. 1, 3, and 4 were operated on successfully by urethral lithotrity and Nos. 2, 5, and 6 by perineal lithotrity—two successfully and one, No. 2, with a fatal result. The first case caused me for a time great anxiety. The condition had not been recognised before operation and the stone had been easily seized and crushed. The débris was passing freely through the evacuator, where I noticed a curious gurgling sound, and on inspecting the abdomen perceived that each injection of water into the bladder produced a swelling evidently outside the bladder cavity. I suspected at once that I had during my manipulations perforated the bladder wall. The extravasation of water seemed, however, so limited that I determined to thoroughly explore with a sound before proceeding to cut down on to the perforation. I managed to introduce the sound into the extravasation, and after careful exploration convinced myself, to my intense relief, that I had to deal with a diverticulum of the bladder. I recognised a stone in the diverticulum, but cannot say whether it was originally there or was a fragment which had been washed up. I introduced a small lithotrite into the sac and crushed the stone, the fragments falling into the general bladder cavity. The patient recovered perfectly. The second case is of importance from many points: (1) the almost complete closure of the sac; (2) the erroneous diagnosis; and (3) the fatal result. The patient was an Egyptian fellah aged about eighty-five years, suffering from a stone in the bladder with very fœtid cystitis, and his general condition was unsatisfactory. I tried to perform urethral lithotrity, but failed to

FIG. 9.



Examples of encysted stones. (Semi-diagrammatic.)

grasp the stone, the movements of the lithotrite being impeded by a tumour which could easily be balanced between the lithotrite in the bladder and a hand on the abdominal wall. Considering the age of the patient, the fœtid cystitis, and general debility I surmised the existence of a bladder growth, probably malignant. I made a perineal incision, crushed the stone, and removed it. I then introduced my finger into the bladder and thoroughly examined the tumour. Its surface was rough and fragments were easily detachable, and I therefore considered my diagnosis of malignant tumour fully confirmed. The patient died a few days later, partly from exhaustion and partly from septicæmia. On post-mortem examination the tumour situated at the summit of the bladder turned out to be a stone enclosed in a sac communicating with the general bladder cavity by a tiny passage through which a probe could only be passed with great difficulty. The whole cavity of the bladder was lined with pendulous granulations due to the presence of innumerable bilharzia embryos. In this case the communication between the sac and the bladder was so minute that the stone could not have been reached by any operation from the bladder cavity. Had an exact diagnosis been possible a supra-pubic operation with incision through the peritoneum into the cyst might have been attempted. Under the circumstances, however, it is doubtful whether the ultimate result would have been different. The third case was diagnosed before the lithotrite was introduced. I am, however, in doubt as to whether this was not a case of stone in the right ureter. On introducing the lithotrite I found, as I had found when sounding, that the stone could not be felt until I had reversed the lithotrite and insinuated its extremities into a cavity situated behind the prostate and to the right of the

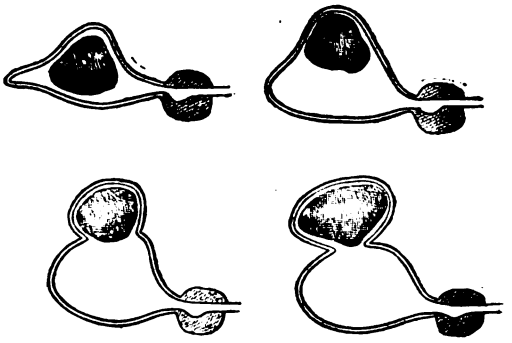
middle line. A finger in the rectum was sufficient to clearly differentiate the limits of the sac and to distinguish it by its position from a post-prostatic pouch. Having guided the jaws of the lithotrite into the cavity of the sac, and carefully controlling every movement by a finger in the rectum, I was able to seize and crush the stone, and after a somewhat prolonged and difficult operation I succeeded in removing all the débris through a curved evacuator. The fourth case was easily treated by urethral lithotrity, the communication being very free between the two cavities. The condition was easily recognised (1) by the position of the stone, (2) by the result of bimanual examination, (3) by the contour of the bladder when distended with water, and (4) by a careful examination of the cavity of the bladder with a sound after operation. The fifth and sixth cases were treated by perineal lithotrity and the condition easily recognised by the finger introduced into the bladder. In both I had tried urethral lithotrity and had failed. The sixth case was particularly interesting. The patient was a boy aged about fourteen years in whom a large stone had been diagnosed. Repeated attempts to grasp the stone with a lithotrite were in vain and I opened the bladder by a lateral perineal incision. The forefinger introduced into the wound entered a large cavity distended with urine. Behind this could be recognised the stone tightly grasped by the bladder. After great difficulty this was seized and crushed and the débris removed. Digital examination then showed that the bladder was divided by an annular constriction into two cavities, anterior and posterior, of nearly equal size. The lower part of this annular constriction stretched from the opening of one ureter to that of the other. The front cavity, therefore, coincided with the trigonal pouch largely dilated; the hinder cavity represented the rest of the bladder. The origin, or rather one possible mode of origin of these diverticula, suggested itself to me in meeting with some of their earlier manifestations. I have seen, as above stated, cases of what I consider to be the first stage of the encapsulating process. This condition is indicated by the stone always occupying a special portion of the bladder cavity. It has frequently happened to me in performing lithotrity to find the position occupied by the stone evidently not depending on gravity. I know of no stone lighter than urine, yet I have often found that a stone was to be felt only at the summit of the bladder, perhaps at the very highest point of that viscus, perhaps a little to one side or the other. In all these cases the stone has always retained the same position, and in most of them I have met with difficulty in grasping the stone with a lithotrite. For some time I failed to see the explanation of this condition until a case occurred in which, having after many attempts failed to grasp the stone, I proceeded to a perineal section. On introducing the forefinger I found that the stone was fixed in its abnormal position by the grasp on it of the muscular walls of the bladder, and it was only with great difficulty that I succeeded in displacing it. Once displaced it fell to the base of the bladder and I crushed and removed it easily. After the removal of the débris I thoroughly examined the bladder bimanually and could find no trace of any cystic formation; the walls presented, moreover, no irregularity or constriction of any kind. Some months later I came across a case (No. 136 on my list) in which a very similar condition existed, with this difference, however, that after the removal of the stone there still remained an evident, though apparently muscular, constriction producing a distinct irregularity in the shape of the bladder cavity. This I consider to have been a slightly later stage of the same condition as existed in the previous case. I consider, also, the sixth case of sacculated bladder to have been a still further development of the same condition, and so on through the other cases up to No. 2, in which the sac had been almost entirely closed off. I attach the principal importance in the production of encysted stone to the contraction on it of the muscular walls of the bladder. I would sketch the history of such a case as follows. The beginning of the story is probably the descent of the stone into the bladder. There it gradually increases in size, producing more or less of the usual symptoms attendant on stone. The bladder becomes irritated and its contractions excessive. For some reason, perhaps during sleep, when the stone probably rests in one place, the muscular contraction becomes such as to grasp the stone. This contraction may be spasmodic or continuous. In the latter case, after a certain time the continuous contraction will gradually tend not only to grasp but to envelop the stone. Those portions of the bladder walls which lie immediately beyond the stone, finding no resistance except their own rigidity, will gradually form an annular constriction, dividing the bladder into two cavities, one of which is occupied by the stone. (Fig. 10.) This muscular action, if continued long enough, and especially when assisted by inflammatory deposits and their secondary contraction, is, I consider, quite sufficient to convert the cavity into a sac communicating by only a small or very small opening with the bladder cavity. It is quite comprehensible even that this opening might become completely closed. I think that there are certainly, therefore,

FIG. 10.



Showing process of encapsulation from muscular contraction. (Diagrammatic.)

two methods at least by which an encysted stone may be produced—the first is by retention of the stone in the ureter and the second by muscular and cicatricial contraction on it of the bladder walls. The first method has been certainly demonstrated by the discovery of stones in the ureter as it pierces the bladder walls. The second method is rendered very probable (1) by its physiological possibility; (2) by the various stages observed in the cases quoted above; (3) by the fact that nearly all encysted stones fill the cyst they occupy; and (4) by the fact that while sacculated bladders from distension are common, cysts are very uncommon except in connexion with stone. The sixth case of encysted stone is particularly interesting on account of the position of the constriction. The lower part of the ring coincided exactly with the strong transverse band of muscular fibres stretching across the base of the trigone from one ureter to the other. The contraction of this band was in all probability the commencement of the encysting process, which extended later so as to completely surround the stone and to produce a double bladder cavity. I have examined many large stones, two in my collection, one of 36¼ oz. and one of 14 oz., one in the collection of Norwich Hospital (a cast), and several in the collection of the Royal College of Surgeons of England, and I have found on the under surface of nearly all of them a groove produced, I think, by the contraction of this transverse muscular band. I think that in many cases the portion of the bladder cavity behind this band contains the greater part of the stone, the portion in front of it forming the imperfectly acting urinary reservoir. This contraction of the muscular coat of the bladder on the stone is, I think, therefore, a great agent in producing a condition of encystment. It is at the same time the means of producing considerable alleviation in the symptoms due to the stone, inasmuch as it largely limits its movements. It has therefore the appearance of being an attempted cure, or rather alleviation, on the part of nature, and helps to explain the prolonged periods for which large stones have been patiently carried by their unfortunate possessors.

3. *Where the stone has been lodged in a retro-prostatic pouch.*—In Egypt prostatic disease is of very rare occurrence, and the number of cases of stone complicated in this way has not in my experience been great. The condition when met with also has been due much more to pouching of the bladder than to an enlargement of the prostate. The pouch in consequence is always largely open and the difficulties presented by it comparatively slight. In fact, I consider that a post-prostatic pouch when largely open is rather a help than a hinderance to the detection of the stone and to the performance both of lithotrity and

Digitized by Google

lithotomy. With regard to detection, if it is made a routine practice to search the post-prostatic pouch it becomes the easiest place to find a stone. In lithotrity the pouch lies open in the most favourable condition for receiving fragments and forms a happy hunting ground for the reversed beak of the lithotrite. In lithotomy the pouch forms a swelling which the knife of the veriest tyro cannot miss. A pouch of this description presents, however, a complication under two conditions. Firstly, it is apt to retain tiny fragments even after very careful washing out. I have found that this may usually be avoided by using a slightly curved evacuator the beak of which is reversed into the sac. Careful washing out, injecting only very small quantities of water very slowly so as not to displace the fragments, is, when combined with equally careful searchings with the reversed sound, almost certainly successful. Secondly, it is apt to retain residual urine during convalescence. For this the simplest treatment is to make the patient pass urine while lying on his abdomen. Should cystitis ensue the bladder must be carefully washed out.

4. *Where the stone has been lodged partly in the urethra and partly in the bladder.*—This condition is uncommon and as a rule presents but little extra difficulty as regards treatment. The symptoms which may lead to a suspicion of the existence of this condition are two: (1) great increase of pain after micturition from contraction of the neck of the bladder on the stone, and (2) complete mechanical obstruction to the passage of any urine. The diagnosis is easily made on passing the sound; the only condition likely to be mistaken for it is the existence of a stone in the prostatic urethra. The treatment in both cases is the same. An attempt should be made to push back the stone into the bladder cavity. This is usually best accomplished by means of a large, straight evacuating tube which, guided and assisted by a finger in the rectum, is made to displace the stone from the depression or dilatation in which it is buried and to push it onwards. No great force must be used in these manœuvres, and should they fail a perineal incision should be immediately practised on to the stone.

There are of course various other positions which may be taken up by urinary calculus. In addition to the usual situations occupied by stones in the kidneys, ureters, prostate, urethra, prepuce, and scrotum, they have occasionally been met with partly or entirely outside the urinary organs. Such cases, however, do not come under the category of bladder stones, to which alone my observations refer, and I shall leave them out of consideration. The question to be decided, therefore, is, given that a stone has been recognised as encysted either by partial retention in the ureter, by sacculation of the bladder, or by a post-prostatic cyst, which is the best method of treatment? With regard to a stone partially retained by the ureter I have already expressed my opinion. When the stone is situated in a sacculus or diverticulum of the bladder the method of treatment should depend chiefly on the relative or actual size of the mouth of the sac. Or assuming the sac to be produced by muscular action, I would state my opinion in this way, that the method of treatment should depend on the stage of development of the sac. In the very earliest stages—viz., in those in which the stone is simply grasped by the contraction of a portion of the muscular walls—urethral lithotrity is plainly indicated. The only difficulty is in getting the first grasp of the stone. This difficulty may as a rule be easily overcome by distending the bladder with water. I have already referred to the methods I employ when crushing a large stone on which the whole bladder is firmly contracted. The conditions existing in the first stage of encystment of a stone are very much the same and the graduated pressure of the hydrostatic douche is equally efficient. After the introduction of a few hundred grammes of water the muscular contraction gives way and the stone drops to the bottom of the bladder either by itself or with slight help from the sound. When the process has arrived at a later stage and there is a definite permanent constriction of the bladder cavity, distension with water is of little avail. If the opening into the sac be large—say, equal in diameter to two-thirds of the diameter of the stone—and if the stone moves freely in the sac, an attempt may be made to perform urethral lithotrity. Such an operation must, however, be conducted with the greatest care and patience. That it is possible is shown by the success of the three cases (Nos. 1, 3, and 4) in which it was performed. It is, however, an operation which should only be attempted by a lithotritist in constant practice. Failing urethral lithotrity, the selection seems to be between perineal lithotrity and suprapubic lithotomy, and I think that each operation is fitted for a separate class of case. Those cases which seem suitable for urethral lithotrity from the largeness of the mouth of the sac, but in which this operation cannot be carried out, may, I think, be treated with a good prospect of success by perineal lithotrity. Those cases which, from the smallness of the opening, are evidently unfitted for urethral lithotrity are equally unfitted for the perineal operation and should, if they are interfered with at all, be treated by suprapubic cystotomy.

(To be continued.)

ON THE CLINICAL VALUE OF DIURETIN.

BY LOUIS VINTRAS, M.D. DURH., B.SC. PARIS,
PHYSICIAN TO THE FRENCH HOSPITAL.

WITH special drugs of this description the difficulty the practitioner meets with is to determine the particular class of cases in which they may be of value. When first introduced these therapeutical agents are given somewhat at random, and most often only isolated cases are reported or the results merely tabulated under a symptomatic heading without any differentiation of the real pathological conditions: hence arises much of the praise which is lavished on indifferent drugs, while others which have a real clinical value are allowed to fall into disrepute, especially so in the case of a drug such as diuretin, which is meant for the relief of a symptom under certain conditions which can only be determined after a long period of probation. Having seen this particular diuretic used in a certain number of cases, I have chosen a few typical cases in which it was given with varied results as the means of furnishing the best indications for further investigations.

CASE 1.—A man aged fifty-seven years was admitted to the French Hospital in September, 1893, with œdema of the lower extremities, marked cyanosis, difficulty of breathing, and scanty secretion of urine. He had been ill for several months and the disease had made rapid progress within the last three weeks. There was a well-developed murmur accompanying the first sound, the pulse was irregular and hard, the superficial veins were congested, and the patient was unable to remain for any length of time in bed. He was ordered digitalis and nux vomica, and improved gradually at first. At the beginning of October the secretion of urine became again much diminished and diuretin was ordered in two-grain doses every hour with good results. The urine, which had been smoky, dark-coloured, and thick, became rapidly clear and increased in quantity. Three days after the beginning of this treatment the patient was passing four pints in the twenty-four hours; he could remain in bed with comfort and slept comparatively well. After five days the diuretin was stopped and larger doses of digitalis substituted. The œdema of the lower extremities, however, continued and punctures were made. The patient rapidly improved, the cyanosis disappeared, the breathing was free, and by the beginning of December he was able to leave the hospital and resume his work.

CASE 2.—A man aged forty-four years was admitted to the French Hospital towards the end of 1893. He was a sturdily built individual, but had been suffering from shortness of breath and pain in the left side over the region of the heart for several years. For the last three months he had been obliged to relinquish his occupation, complaining mostly of a hard, hacking, dry cough, a sense of oppression over the chest, and sleeplessness. He could not keep the horizontal position and passed most of his time in an arm-chair, bent forwards, with his head reclining on the side of the bed. The physical signs consisted in a loud murmur accompanying the second sound and a jerky, hard pulse with occasional intermittency. The urine was thick and coffee-coloured, with a heavy deposit, and contained a small amount of albumin, while the quantity of urine varied greatly, but was at times very scanty. The case was one of aortic regurgitation. He was put on digitalis and nux vomica, with a mixture containing codeia and oxymel scillæ to relieve the cough. The digitalis had only a transient action; at the end of ten days it failed to give any relief

Digitized by Google

and was abandoned. When resumed a fortnight later the patient seemed to improve, but about a month after his admission he became much worse and the quantity of urine rapidly diminished. He passed only a few ounces at a time and sometimes not half a pint in all in twelve hours. The œdema of the lower extremities also rapidly increased. He was then ordered two grains of diuretin every hour. The drug acted well. In the first twenty-four hours the patient passed over two pints of urine. It was still thick, but improved on the second day; on the third day it amounted to between three and four pints. After four days the œdema had almost entirely disappeared. Tincture of strophanthus was then substituted. The general condition had also greatly improved; the patient slept well and was able to remain in bed without inconvenience. He felt so much better that a fortnight later he asked to leave the hospital. The amelioration, however, could only be temporary, and I heard that he died about three months later.

CASE 3.—A man aged thirty-seven years had been suffering for nearly two years with disease of the liver—hypertrophic cirrhosis. He had been able to work until a fortnight before admission to hospital, when he was seized with pains in the loins, a general sense of malaise, and nausea; he noticed that his eyelids were puffy and his ankles swollen. He rapidly grew worse and had to keep to his bed. On his admission he had marked symptoms of uræmia and had scarcely passed any urine for the previous two days. There were œdema of both legs and pitting on pressure, the abdomen was distended with fluid, and there were twitching of the muscles of the face and hands and low muttering delirium with lucid intervals. The urine contained albumin, but not in large quantities. He was given two grains of diuretin every hour combined with a mixture of nitrate of potash and acetate of ammonia. Six hours after admission he passed eight ounces of urine and a few hours later ten ounces. The case was hopeless from the beginning, and the symptoms were such that he never rallied but died the next morning.

CASE 4.—This patient was a man aged thirty-nine years who had not felt well for several months previously to his admission to hospital. Three weeks before he had an attack of influenza, and a few days later had felt pains in his shoulders, left side, and over the loins. After a week his abdomen began to swell, and a day or so later his legs and scrotum. He noticed that his urine was thick and that the quantity passed was diminishing. On admission the abdomen was found to be enormously distended, there was anasarca of the lower extremities extending up to the groin, and œdema of the scrotum and penis. The tongue was furred and dry, the temperature was normal, and the heart was sound. The right lung was healthy. On the left side there was slight pain along the left axillary line and slight dulness over the same region. The urine was coffee-coloured, with a thick deposit of phosphates, and contained one-fifth albumin. Under the microscope large hyaline and epithelial casts were seen. After eight days, as there was no improvement, diuretin was given in the same way as above, but after five days it had produced no appreciable result and was abandoned.

CASE 5.—The patient was a young girl who had been suffering from disease of the kidneys for over four months and who on admission to hospital had all the signs of large white kidney following an acute attack of parenchymatous nephritis. The face was puffy and fatty, and she was suffering from advanced dropsy. The urine contained large irregular hyaline casts, blood corpuscles, and pus cells, and was almost solid with albumin. In this case diuretin was given without producing any effect whatever.

As stated above, in considering the value of a therapeutical agent of this kind it is not the ultimate termination of the case which should form the basis of judgment, but its effect on an individual symptom. Such a drug as diuretin cannot pretend to be a specific treatment in any disease, and its action can only be exerted for the relief of a distressing complication. Reviewing, then, the results of these cases it appears that when the kidney affection is primary and well established—that is, when the deep parts of the organ are affected, as in the parenchymatous form of acute nephritis—and when there is much albumin present, diuretin is of little or no value, while in those cases in which the kidney trouble is secondary to morbid lesions in other organs and the epithelial layer of the urinary tubules in the seat of disease, this diuretic is a valuable therapeutical agent.

Hanover-square, W.

CANCER OF THE RECTUM: TREATMENT, OPERATIVE OR PALLIATIVE.

BY HERBERT W. ALLINGHAM, F.R.C.S. ENG.,
SURGEON TO THE GREAT NORTHERN CENTRAL HOSPITAL; ASSISTANT SURGEON TO ST. GEORGE'S HOSPITAL.

AFTER a considerable experience of cases of cancer of the rectum I think that it may be useful to discuss the question of the treatment, operative or palliative, of malignant disease affecting this part of the body. One reason for making this review is the fact that some authorities appear to hold that all cases of cancer of the rectum demand either excision or colotomy quite irrespective of many points which require careful attention. Thus cases sometimes come to one in which excision is requested when colotomy should really be done, or *vice versâ*, or, again, when neither operation is needed. It must not be inferred that I am in any way opposed to excision of the rectum or inguinal colotomy, for they are excellent operations, and when employed in suitable cases afford great relief to the sufferer and are highly satisfactory from every point of view. My intention is merely to show that, useful as they are, they should not be used or brought into disrepute by being employed in all cases of cancer of the rectum. During the last eight years I have seen about 720 cases of this malady, having performed excision 62 times and colotomy 138 times. I have thus been led to make a mental classification of the cases according to the various lines of action which should be pursued. In arriving at this classification the following points must be kept prominently in view: (*a*) the age of the patient; (*b*) the position and extent of the growth; and (*c*) the nature of the symptoms—viz., obstruction of the bowels, constant diarrhœa, hæmorrhage, or pain. By this classification cases of cancer of the rectum may be divided into those which are fitted for excision, for colotomy, or for palliative treatment.

The question of age is a most important matter. If the patient's age does not exceed forty-five years I make bold to say that very little is to be gained by excision, even if the growth is within a reasonable distance from the anus. It appears that after excision in such cases the malignant disease returns, often before the wounds resulting from the operation have healed. In two or three instances, however, I have excised both the growth and the recurrence, and in one case after repeated excision of the recurrence the malady ceased to return; but this case must be taken as an exception to what may be called the rule. Again, colotomy seems to prolong the patient's life for an extremely short period. Indeed, unless the surgeon is absolutely driven to perform colotomy palliative treatment is the right course to pursue. In patients between forty-five and sixty years the prognosis as regards excision is more favourable, and this operation should be attempted when the growth is well to the lower part of the rectum. In this class colotomy for disease high up the rectum should be performed only when the symptoms presently to be described are well marked and when palliative treatment has failed to afford relief. For patients above sixty years excision is extremely favourable in suitable cases, and should always be attempted when there is a fair chance of a thorough removal of the growth. The remarks with regard to colotomy are the same as those applied to patients between forty-five and sixty years. It will be readily seen from the above classification that the older the patient becomes the less rapidly does the malignant disease grow and the less likely is it to recur.

The next points for consideration are the position and extent of the growth. For practical purposes the question of position may be sub-divided as follows: (*a*) When the disease is near the anus and healthy mucous membrane can be felt above the growth; (*b*) when the growth is higher up the bowel, but can be easily felt and is freely movable, although its upper limits may not be readily definable; and (*c*) when the growth is quite high up the rectum—i.e., at the junction with the sigmoid flexure—and can only just be felt by the finger. In the first class the growth, if movable, should be freely excised. In the second class Kraske's

Digitized by Google

operation may be performed if the patient consents to undergo it on learning of its serious nature and the danger he may incur. In cases falling under the third sub-division colotomy is certainly a justifiable proceeding if the symptoms warrant the necessity.

To return to the symptoms. With regard to obstruction, if the case is one fitted for excision the constipation may be relieved by free excision of the growth. If, however, the tumour is so high up as to negative excision, and if it has been found impossible to remedy this obstructed condition by the use of mild laxatives, colotomy should not be delayed for one moment. To postpone colotomy when the case is in such a state only entails much suffering; further, the delay may prove a great source of danger, for the gut may give way above the seat of obstruction or the patient may, so to speak, be poisoned by fæcal accumulations. Moreover, when the colotomy has eventually to be performed it is rendered much more difficult to do, and thus an operation which really is extremely easy may by tardiness be converted into a grave and dangerous proceeding. Constant spurious diarrhœa is another symptom frequently complained of by patients suffering from cancer of the rectum. When it is due to a growth within the excisable region it may be cured by an excision. But if that operation is out of the question, and if one has failed to remedy this wretched and distressing condition by treatment with various forms of opiates, laxatives, and so forth, then and then only is it justifiable to perform colotomy in order to give the patient relief. The same remarks apply to the other symptoms—viz., to frequent hæmorrhage or to constant pain.

As was stated at the outset, I do not consider that all cases of cancer of the rectum should be treated either by excision or colotomy. I have met with many patients who have been advised to undergo colotomy, but who by careful and judicious treatment have been enabled to continue at their respective occupations without this operation being necessary for some considerable time. There are some who advise colotomy in nearly all cases of cancer of the rectum which come before them, imagining that by diverting the fæces they may succeed in arresting the rapidity of the growth. This I do not believe to be in the slightest degree the case. The patients referred to above, when their malady has been judiciously treated, lived quite as long as they would have done if colotomy had been performed in the early stages of the disease. One last remark must be made. In cases of cancer high up the bowel it may be necessary to starve a patient or at least subject him to what is practically starvation in order to keep him comfortable. In consequence of this starving the patient may become exceedingly emaciated and may perhaps express the opinion that the treatment is worse than the disease. In such a case I should without any hesitation perform colotomy so that the local symptoms—viz., obstruction—may be obviated. When this has been done the patient can eat and drink as he chooses and, as a rule, rapidly puts on flesh and recovers his general health for a time—that is to say, until the malignant disease begins to attack other important organs.

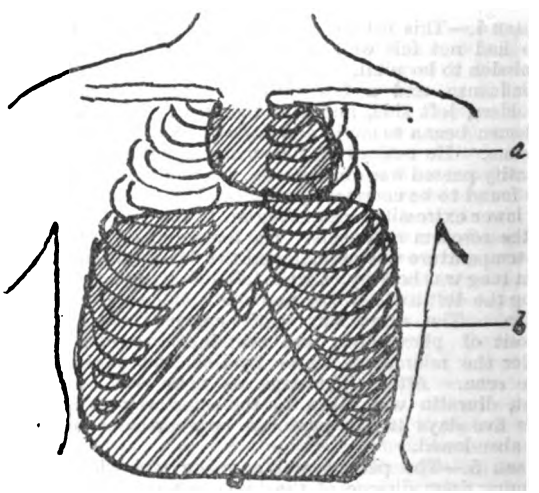
Grosvenor-street, W.

LARGE HYDATID TUMOUR OF THE LEFT PLEURAL CAVITY SIMULATING HYDATID DISEASE OF THE LIVER; OPERATION; RECOVERY.

BY ARTHUR P. LUFF, M.D. LOND.,
PHYSICIAN IN CHARGE OF OUT-PATIENTS AT ST. MARY'S HOSPITAL.

THE patient, a married woman aged thirty years, was admitted into St. Mary's Hospital under my care on Jan. 8th, 1895, complaining of shortness of breath and severe pain in the left side of the chest. She stated that in 1875, when she was ten years of age, she was tapped, and in 1884, when she was nineteen years of age, she was tapped in the epigastrium, after which she remained well for several years. Unfortunately no medical account of these tappings is obtainable, but as the patient stated that at the time of the second tapping she was questioned on the subject of contact with dogs, the presumption is that she was then suffering from hydatid disease. She lived at the time with her uncle, who in 1873 was tapped three times in St. George's Hospital; in 1884 her uncle "brought up" a quantity of fluid and died whilst being conveyed to the same hospital. This would suggest a common origin of the disease. Seven months previously to admission she noticed that she was increasing in size above the waist, and about the same time she experienced tenderness on the left side and front of the chest. Two months before admission she began to suffer from shortness of breath, and the pain on the left side of the chest gradually assumed a shooting character and became very severe, shooting up to the left shoulder and down the left arm. During the three or four weeks preceding admission she fainted a few times and had occasional shivering fits. Seven days before admission she had a slight attack of jaundice, which, however, soon passed away. Five days before admission she was seized with severe shivering fits, great pain in the left side of the chest, dyspnœa, and vomiting after food. When this attack had lasted about five hours she coughed up about a pint and a half of clear fluid of a pale yellow colour, which gave her immediate relief, but a few hours later the pain and dyspnœa returned, although the symptoms were less urgent than before. On admission the patient presented a somewhat wasted appearance; there was considerable dyspnœa, accompanied by a hard, dry cough, but no cyanosis. The left side of the chest was very painful and tender; the temperature was 101° F., the respirations were 40, and the pulse was 100. She stated that the swallowing of food was somewhat difficult, the difficulty being experienced at a point about half-way down the œsophagus. On inspection a large tumour was seen causing marked prominence of the epigastric, both hypochondriac, and the upper portions of the umbilical, and both lumbar regions, reaching below to the umbilicus. (Fig. 1.) The surface of the tumour

FIG. 1.



a, Heart. *b*, Hydatid cyst.

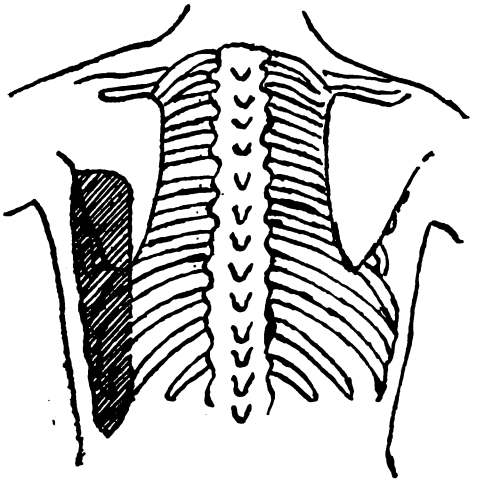
was hard and smooth. Distinct fluctuation could be felt in two or three places, but no thrill was obtainable. The tumour moved with respiration. Percussion dulness was obtained over the left part of the chest up to the first intercostal space; in the mid-axillary line on the left side dulness extended from below upwards to the fifth rib. This dulness extended at the same level over the lower part of the back of the chest on the left side as far as a line dropped vertically from the inferior angle of the left scapula (Fig. 2), inside which line a fairly resonant lung note was obtainable. Over the right front of the chest percussion dulness extended upwards to the fourth rib (Fig. 1) and to a corresponding level in the axilla. Over the whole of the right back a resonant lung note was obtainable. No breath sounds could be heard on auscultation over the entire dull area, and vocal fremitus could not be obtained. The heart was pushed considerably upwards (Fig. 1) and could be felt beating on the left side of the chest, the maximum impulse being obtainable in the second left intercostal space. The cardiac dulness was continuous with the dulness below, and extended a finger's breadth to the right side of the manubrium. The

Digitized by Google

heart sounds were normal. The urine was of specific gravity 1030, acid, and free from albumin and sugar. The pint and a half of clear fluid coughed up five days before admission were evidently due to rupture of a cyst into the lung, and the temperature of 101° on admission was probably caused by the rupture. The absence of hæmoptysis—often an early symptom of pulmonary hydatid disease—and the fact that the heart was displaced directly upwards and not pushed to the right side, were indications that the growth was not a primary one of the left lung or pleura; moreover, there was no deficiency of thoracic movement on the left side, as there generally is in pulmonary hydatid disease. My diagnosis was extensive hydatid disease of the liver, with probable extension of the disease into the left pleural cavity. Mr. Silcock, who saw the case with me, agreed with this diagnosis and decided to operate.

Ether was administered and Mr. Silcock opened the abdomen by a four-inch incision in the middle line between the ensiform cartilage and the umbilicus. The fleshy-looking cyst wall was exposed bulging downwards into the

FIG. 2.



abdominal cavity. An effort was made to draw off some portion of the fluid from its interior by means of aspirator needles and ovariotomy trocars. These instruments speedily became blocked; hence, having so disposed a number of sponges that the general peritoneal cavity would be thereby exempted from infection the cyst wall was freely incised. Immense quantities of daughter cysts escaped, their eviction being greatly facilitated by using a stream of sterilised water (temperature 100°) projected into the cyst through a glass tube tipped by a short indiarubber one in connexion with an irrigator cistern; the pressure of the fluid could easily be regulated by raising or lowering the latter. Much time was thus spent, the irrigation being continued until the contents of the cyst had been thoroughly cleared out. The long glass tube was most useful in that the depths of the cyst beyond reach of the finger-tips were easily reached by its means. The cavity of the cyst being packed with large sponges, its connexions were examined. That portion of the cyst wall incised was indistinguishable from the left lobe of the diaphragm, the latter having been displaced downwards by the cyst occupying the left pleural cavity. The left lobe of the liver lay to the right of the mid-line, atrophic and shrunken from pressure. Air whistled in and out of the opening into the cyst with the respiratory movements and the subserous tissues below the diaphragm near the spine became emphysematous. The peritoneal surface of the cyst wall was united to that of the edges of the parietal wound and the latter partly closed, a large drainage-tube being passed deeply into the cyst. The weight of the cyst walls removed amounted to six pounds four ounces; the amount of fluid was computed to be six pints. The subsequent course of the case requires but slight notice. The wound remained aseptic, the cyst being frequently washed out, and drainage was effected by keeping the patient lying on her right or left side or in the prone position.

Remarks.—The great surprise at the time of the operation was to find the liver normal in size. The well-defined lower edge of the tumour that before the operation could be felt reaching to the level of the umbilicus was evidently due to the diaphragm having been pushed down by the hydatid tumour situated within the thoracic cavity. During and after the operation the entry of air into the cyst cavity during inspiration (the right half of the diaphragm was certainly not paralysed) was an indication that the cavity was above the diaphragm. The proofs that the cyst was connected with the liver were: (*a*) that a quantity of bile came away from the wound for some time; (*b*) some of the daughter cysts were bile-stained; and (*c*) the parent cyst wall contained columnar epithelium and fibrous tissue, and the source of the former might have been the biliary ducts or gall-bladder. The probability is that originally the woman suffered from hydatid disease of the liver and that some of the daughter cysts passed through the diaphragm into the left pleural cavity from the parent hydatid in the liver.

Weymouth-street, W.

DEATH UNDER CHLOROFORM.

BY J. HOPKINS WALTERS, M.R.C.S. ENG.,
SURGEON TO THE ROYAL BERKSHIRE HOSPITAL.

THE following two cases, one of death and the other of threatened death while under chloroform, seem to be worthy of record.

CASE 1.—A boy aged six and a half years was anæsthetised by chloroform on March 27th, 1896, for the removal of tuberculous cervical glands. In other respects he seemed to be healthy and had returned only a few weeks previously after being five months at the seaside. The operation was performed at 10.30 A.M., a breakfast-cupful of beef-tea having been taken at 8 A.M. in lieu of breakfast. The glands were large and numerous; the surrounding tissues were infiltrated and unusually vascular, rendering the dissection down to the sheath of the vessels delicate, difficult, and prolonged. There was free hæmorrhage, amounting, probably, to three or four ounces (but this is always most difficult to estimate; it possibly might have been more, not much). The operation was almost finished when sudden arrest of oozing from the raw surface was noticed to take place, while at the same moment the experienced anæsthetist who was kindly giving the chloroform drew attention to the patient's pallor. I give in my friend's own words the notes he has made on the case: "The boy had been under chloroform for about forty-seven minutes, during which time he took the anæsthetic in a manner that gave rise to no more than ordinary anxiety. The first unfavourable sign noticed by me was a sudden and extreme pallor, not the bluish grey of respiratory failure, but a deathly whiteness. After a few seconds the breathing stopped. Immediately the radial artery was felt, but there was no pulse. The heart was auscultated, but there was no pulsation. Artificial respiration was at once performed, with the result that a very irregular sighing or gasping respiration was established. During the artificial respiration the air entered and left the lungs quite freely. The tongue was pulled out forcibly with tongue forceps and kept out while artificial respiration was maintained for three-quarters of an hour; nitrite of amyl was administered, and brandy and strychnia were hypodermically injected." In addition to the above friction was made over the heart while the head was depressed and the body raised, but all to no purpose. The child was dead.

The case of threatened death under chloroform presents similar features to the above fatal case, but was followed by a happier result.

CASE 2.—A child aged seventeen months, the subject of large double inguinal congenital hernia, was put under chloroform for the operation of radical cure. The child took the anæsthetic well and was fully under its influence when the incision was made. Two sweeps of the knife were followed by the application of a sponge, and on making the third sweep I noticed that blood ceased to flow. Looking round I found the child deathly white and apparently dead. Neither radial pulse nor heart pulsation could be felt. Artificial respiration was at once performed, the pulse returned, and in a few minutes the child had so well recovered as to enable me to complete the operation I had begun. In consequence of this *contretemps* I decided to postpone

Digitized by Google

operating on the other hernia until after recovery from this operation. Owing to a little gastric disturbance the second operation was not performed for two months, and previously to the chloroform being given I warned the administrator, who had also been the chloroformist on the former occasion, to take especial care on account of the previous narrow escape. At the same stage of the operation apparent death recurred in a manner precisely similar to the previous occasion, with like treatment and fortunate result, followed, as before, by completion of the operation. This time we all were quite on the alert, and were thus able to make sure that it was a case of heart failure, the pulse stopping before respiration ceased.

These two cases present the following identical features: (1) both were children within the age at which chloroform can be given with the greatest immunity from accident; (2) auscultation indicated a sound heart in each case; (3) on each occasion a Skinner's inhaler was used; (4) in neither instance was the operation commenced before the conjunctival reflex had disappeared; (5) in each the first indication to the operator was blanching of the wound coincidently with the observation by the anæsthetist of sudden general pallor; and (6) uniformly the cause of death and threatened death was cardiac failure. The differences between the cases are that while the fatal case showed no unfavourable symptoms until the end of the operation the other exhibited them at the beginning: the one had taken a quantity of chloroform and the other little; the one had suffered loss of blood and shock from the operation and the other none. These probably were the determining factors between death and recovery. On comparing with the "respiratory failure" dictum from Hyderabad the statistics of THE LANCET Commission appointed to Investigate the Subject of the Administration of Chloroform and other Anæsthetics from a Clinical Standpoint,[1] one is struck by the enormous majority of reported primary pulse failures, which, together with the numerous cases of accident occurring in the very earliest stage of chloroform administration, indicate that much has yet to be learned of the causes of these calamities. The observations of Rosenberg and Guérin seem to throw on them some light, and their conclusion that respiratory and cardiac depression are due to reflex rather than direct action deserves careful investigation. Certainly, until such conclusion is negatived or confirmed the suggestion to avoid nasal inhalation or to neutralise the local effect of chloroform by thorough cocainisation of the nasal cavity is worthy of universal adoption. That ether is so much safer than chloroform as to outweigh the great advantages of the latter has still, I think, to be proved after the honest tabulation of its delayed disastrous after-effects.

NOTES ON A CASE OF COMBINED SCLERODERMA AND RAYNAUD'S DISEASE.

BY J. A. HENTON WHITE, M.B. DURH.,
SURGEON TO THE BIRMINGHAM GENERAL DISPENSARY.

THE following case appears to me worthy of note as throwing additional light on certain cases of scleroderma and indicating a possible etiological connexion between these and Raynaud's disease.

A married woman aged forty-four years sent for me on account of a hardening of the skin in various parts of the body, rheumatic pains in her joints, and attacks of "dead fingers." On examination I found that the integument of the face and forearms, and to a less extent of the arms, thighs, abdomen, and chest, was thickened and indurated. It could not be pinched up from the subjacent tissues and the natural folds and wrinkles were for the most part obliterated. On the forearms, where the contraction of the thickened skin had gone so far as to painfully compress the bones and tissues, the colour of the surface was rather brown. The appearance of the chest was white and cicatricial, whilst the epidermis of the legs and the lower part of the body was covered by coarse flakes not unlike psoriasis. The case was, in a few words, a well-marked one of that affection described by Fagge as scleriasis diffusa and now usually termed scleroderma.

[1] THE LANCET, March 18th and 25th, April 15th and 22nd, May 6th and 20th, and June 17th, 1893.

In addition to these integumentary changes were arthritic lesions, many of the large joints, and notably the temporo-maxillary articulations, exhibiting the coarse crepitus of arthritis deformans. Perhaps the most interesting point about the case, however, was the occurrence of frequently repeated syncopal attacks in the fingers and hands. These attacks came on "twenty or thirty times a day" after the least exposure to cold. The woman had suffered from syncopal attacks in one of the fingers of the left hand for many years. Three years ago she had an eruption of "heat lumps" on the arms, face, and legs, which itched and smarted considerably. These soon became blebs and lasted about six months before finally disappearing. One and a half years ago another eruption of "heat lumps" appeared on the forearms and legs, but on this occasion no blebs formed. Accompanying those on the legs there was considerable œdema. These "heat lumps" had since this time frequently recurred, and gradually the skin had become hard, first in the forearms and then in the face, legs, &c. At times the induration had spread, but the extension had been preceded by the appearance of the lumps. With the first occurrence of the "heat lumps" (one and a half years ago) she also began to have symmetrical vaso-motor spasms in both hands, and lately these phenomena have been very frequent. A few months later her joints became affected, and now she is much crippled in her movements and has especial difficulty in mastication.

Regarding this case from a pathological standpoint it seems possible that the scleroderma, which is anatomically a simple overgrowth of fibrous tissue in the deeper layers of the dermis, may be due to a chronic inflammation resulting from an intermittent blood-supply. This vaso-motor factor may be also assisted by a want of proper trophic stimuli to the tissues affected—here the skin and joints. The initial heat lumps and blebs, as also the œdema, are all occasionally present in Raynaud's disease. Bristowe speaks of a persistent eruption of wheals or erythematous tubercles, in connexion with which vesicles and blebs may be developed, as occurring in this latter disease. Another argument in favour of a vaso-motor explanation of scleroderma is found in the fact that both diseases occur in those classes of patients whose vaso-motor apparatus is very active—namely, women and young people. With regard to treatment the application of warmth to the affected part as a preventive of the spasms, and galvanism with the anode placed in the hand and the kathode on the spine during the spasms might be tried. Medicinally, drugs producing arterial dilatation seem to be indicated. Those, too, which are not too evanescent in their action should be chosen. My patient is at present on jaborandi and salicylate of soda and is taking fifteen minims of the tincture with fifteen grains of the salicylate three times a day. This treatment has produced no sudoresis at present. Jaborandi, however, I hardly consider the ideal drug as it is somewhat irritant to the kidneys, which in skin cases are apt to be irritable. Thyroid extract might be useful, as it certainly, in my experience, causes sudoresis and lowers blood pressure, and I intend to try this if there should be any spread of the disease under the jaborandi. Of course, when the fibrous tissue is once laid down its complete disappearance is very improbable. Massage, however, might render the skin more pliable.

Birmingham.

DURHAM UNIVERSITY MEDICAL GRADUATES' ASSOCIATION.—A large number of the members of this association resident in the metropolis dined together at the Café Royal, Regent-street, on April 17th, under the presidency of Dr. Arthur H. Robinson, the President of the association. The réunion was a pleasant one, and the association was honoured by the presence of several guests, the invitation having been extended to graduates of the University outside the association.

HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S-PARK.—At the annual meeting of the governors of this institution the Earl of Carnwath, speaking from the chair, stated that the annual report showed an increase in the work and a diminution in the contributions. He referred to the fact that in four years the lease of the present building would expire, and a new building, involving the creation of a building fund of some £10,000 or £15,000, would soon become a pressing necessity. He hoped that some munificent gift would soon be forthcoming towards this object.

ST. GEORGE'S HOSPITAL.

A CASE OF ACROMEGALY TREATED BY PITUITARY EXTRACT; REMARKS.

(Under the care of Dr. H. D. ROLLESTON.)

THIS case is a typical one of acromegaly and differs but in degree from the majority of recorded cases. The remarks of Dr. Rolleston remind us how very far we are at present from understanding the exact nature of this disease, and no apology is required for bringing a carefully observed case before our readers. We regret that it is necessary to record another failure in the treatment with pituitary extract. At present the extract has not had a very extensive trial; little encouragement for the future is, however, given by our present experience of it. There are certain lines along which investigation should proceed and certain questions which require answers. We want to know if there is any relation between the thyroid gland and the pituitary body, also what the relation is between these two bodies and the nervous system, before we can make very definite progress. In many recorded post-mortem examinations the thyroid gland as well as the pituitary body has been described as diseased. Dr. Bonardi[1] found no tumour of the pituitary body, but atrophy and sclerosis of the thyroid gland in a case examined by him.

A married woman aged thirty-four years, who had been under the care of Dr. Hollis of Wellingborough, was admitted into St. George's Hospital on Feb. 11th, 1896. She dated her illness from her last confinement in August, 1891. Since then she had suffered from fatigue on slight exertion and had had amenorrhœa. But the first definite symptom of acromegaly only appeared in the early part of 1894, when her sight began to fail, and she noticed that her hands and feet were increasing in size. In less than a year she became blind in the left eye, and at the same time her hands and feet became painful both at night and on exertion. For the last two years she had perspired much over the body and limbs, less over the face, and had felt warm even in the coldest weather, so that she had been obliged to wear thin clothing. Since 1891, and especially in the last nine months, she had been getting much stouter. Her sleep had not been so good during the last two years as it was formerly. There was no history of rheumatism or syphilis. She had suffered from headache for twelve years and there had not been any increase of it in recent years. The face was somewhat expressionless and elongated; the skin was of a dingy colour, somewhat coarse, and the subcutaneous tissues apparently thickened; the lips were not specially affected, but the tongue was large and flabby; the nose was prominent and generally enlarged, and there was a considerable degree of prognathism; the hair was coarse, thick, and did not fall out. Of the eyes, the left was quite blind and there was no pupil reflex; the right had very imperfect vision on the nasal half of the field; hemiopic reflex was present, and the nasal half of the field of vision was blind. There was well-marked primary optic atrophy with some irregularity of the discs on both sides. There was no sign of past neuritis or retinitis. There was slight exophthalmos on both sides, and the eyelids were somewhat swollen. The special senses of smell, taste, hearing, and touch were normal, and the voice was natural. The patient was of fair intelligence and showed no sign of nervousness or mental instability—in fact, she was rather phlegmatic than otherwise. The hands were characteristically affected, the phalanges being enlarged together with the overlying tissues, and justifying fairly the comparison to sausages. The wrists were enlarged, while the elbows, shoulders, and clavicles were unaffected. A marked feature was the very considerable loss of power in the hands. The patient had suffered from childhood from talipes equino-varus with some degree of pes cavus. The toes were enlarged, especially the great toes. The ankles were enlarged. The knee-jerks were present. Kyphosis was but slightly marked. The thyroid gland appeared normal and the heart and lungs were normal. There was no post-sternal dulness. The specific gravity of the urine was 1010 to 1020, it contained no albumin but 2 per cent. sugar, which, however, disappeared two weeks before she left the hospital. Dr. Hollis said that there was no glycosuria when she was under his treatment, so it was probably transient. The amount of urine varied from twenty-eight to eighty ounces. She had been in the habit of getting up at night to pass her urine, so there had been some polyuria. The temperature was normal throughout her stay in the hospital. During the month that the patient was in the hospital she was treated with tabloids of pituitary extract (5 gr.) three times a day, and when headache and pains in the limbs were urgent occasional doses of phenacetin (10 gr.) were given. Under the conditions of rest, good food, and the above treatment the pains in the head and limbs were diminished and the glycosuria passed off. The patient herself thought that, inasmuch as she could feel her knuckles more distinctly, her hands were getting smaller; but a comparison of the careful measurements taken on admission and before leaving the hospital by the clerk of the case, Mr. E. L. Hunt, showed that there was a uniform increase in all, or nearly all, the measurements. The effect of pituitary extract therefore seemed to be almost entirely negative. The question of removal of the pituitary tumour was discussed with Mr. Sheild, but the risks and dangers on the one hand and the somewhat hypothetical advantage that would accrue on its successful performance on the other did not seem to warrant its being proposed to the patient.

Remarks by Dr. ROLLESTON.—The case is a fairly typical one of acromegaly and there are only two points in the *clinical* features worthy of special notice. 1. The rapid development of optic atrophy as the result of pressure exerted by the enlarged hypophysis cerebri. The symptoms of acromegaly had only been noticed for two years and at the longest calculation the morbid changes cannot be dated back further than her last confinement in 1891, after which the menses ceased. 2. The presence of sugar in the urine; this has only been noted in a small minority of the recorded cases, though in some there has been definite diabetes mellitus. The glycosuria has usually been found to be easily controlled; in this case no restriction of diet or special treatment (other than the pituitary extract) was employed, and no sugar was present for the last two weeks of her stay in the hospital. As regards the *pathology* of acromegaly, while optic atrophy, when it occurs, and headache may be the local or mechanical effects of the enlarged pituitary body, the essential symptoms are presumably due to some alteration in the internal secretion of the gland. The internal secretion might conceivably be modified in three different ways. I. Suppression—a condition of pituitary inadequacy analogous to myxœdema or Addison's disease. The morbid condition necessary to bring this about would be either atrophy of the pituitary gland, which is not in accordance with the observed facts, for the gland has been almost always found to be enlarged in acromegaly, or destruction by a tumour. In their exhaustive paper on the Pathology of the Hypophysis Cerebri, Boyce and Beadles[2] describe a case of acromegaly with a cystic hypophysis cerebri, but the other cases of tumour given by these writers did not show signs of acromegaly. That simple absence of the internal secretion is not the entire explanation of acromegaly is strongly suggested by the disappointing results of giving pituitary extract. II. Hypersecretion due to excessive activity. Souza-Leite[3] describes the change in the gland tissue as being one of simple hypertrophy. This observation is in favour of the view that the symptoms are due to hypersecretion. If this be true, administration of pituitary extract should only exaggerate the symptoms, but the observations of Ransom[4] and Marinesco[5] show that it has practically no effect, while in a case under the care of Sir William Broadbent[6] there

Digitized by Google

appeared to be some improvement. Oliver and Schäfer[7] find that pituitary and thyroid extracts have opposite physiological effects. Pituitary extract resembles in its action that of the suprarenal capsules, though there are points of difference. Thyroid extract has been found to exercise a curative effect in a case of acromegaly recorded by A. H. Benson.[8] Murray,[9] however, thinks it doubtful whether thyroid extract has any specific effect on acromegaly; this opinion is endorsed by Osler.[10] It is not improbable that any good it does is by influence on the general health. If acromegaly were due to a hypersecretion of the normal internal secretion of the pituitary body, the administration of pituitary extract should intensify and giving thyroid extract should remove the symptoms. If this is not the case—and it does not appear to be so—hypersecretion on the part of the pituitary gland cannot be regarded as a satisfactory explanation of acromegaly. III. Perverted function due to a heterogeneous transformation of the structure of the pituitary body (Marinesco). But in what direction the secretion is perverted is a matter of speculation. Three alternatives may be suggested. 1. The secretion might be deficient in an active principle the function of which is to restrain exuberant growth in the extremities. This, perhaps, is rendered improbable by the general failure of pituitary extract when given medicinally, and there is of course no evidence that irregular growth is spontaneously likely to occur if not kept in check. 2. The abnormal secretion might contain some toxic principle which stimulated the tissues to overgrowth. That the disease is a toxæmia receives some support from its points of resemblance to hypertrophic pulmonary osteo-arthropathy. Marie suggested that the changes in the limbs characterising the latter disease were due to the local action of poisons absorbed from the pulmonary lesions. 3. It might be thought that owing to alteration in the secretion of the pituitary the equilibrium and interaction between it and other internal secretions are disturbed. Possibly some toxic body such as was suggested in the preceding alternative might be thus produced. The thyroid and pituitary glands have been thought to be compensatory; recently they have been shown by Schäfer and Oliver to be physiologically antagonistic. Superficially there are some resemblances between acromegaly and myxœdema, and it might be thought that acromegaly is the result of a disturbance of a chemico-physiological equilibrium maintained in health by the normal activity of these two glands. Such a consideration suggests that acromegaly might be benefited by giving pituitary and thyroid extracts at the same time. The dose of the two extracts should be varied so as to get the desirable mean, but at first, perhaps, a larger quantity of the pituitary extract should be given. The failure of pituitary extract to ameliorate the symptoms of acromegaly is then somewhat in favour of the view that the cause of the disease is perverted and not suppressed or exaggerated functional activity of the gland.

BOLTON INFIRMARY.

A CASE OF TRAUMATIC VENTRAL HERNIA AND ONE OF HÆMOPHILIA.

(Under the care of Mr. GABSTANG.)

TRAUMATIC ventral hernia of the kind described in the first case is of very unusual occurrence—in fact, it has received little notice in our general text-books. Such a hernia, as the result of direct subcutaneous injury, may develop immediately in consequence of rupture of the muscles in the abdominal wall, the protrusion taking place through the opening made, or atrophy with resulting weakness may ensue at the point injured and a hernia develop secondarily. Examples of the former are given by Gay, Meckel, and Bryant. The patient under the care of Gay had a blow from a buffer in the abdomen, and on dissection some of the viscera were under the skin and had come through a rent which divided the left rectus and left epigastric artery, the linea alba, and part of the right rectus. Included in the term traumatic, and much more common than those already referred to, are the hernias which protrude through the scar resulting from the wound made by a surgeon for the removal of an abdominal tumour or for the evacuation of an abscess, also wounds of the parietes received in other ways by stab or gunshot. We are still in a condition of uncertainty as to the exact deviation from the normal which produces hæmophilia, and the facts that are known about it, such as its hereditary character, its more frequent appearance in the male, and also that it is congenital, do not help us in respect to the treatment of the hæmorrhages which are so apt to prove fatal. It is probable that antiseptic treatment with pressure will do more for the arrest of hæmorrhage in these cases than was formerly possible. When the wound suppurated and hæmorrhage frequently recurred from it the attempt to apply pressure or the application of styptics only seemed to make the wound a larger one and the fever more intense. Of the numerous drugs which have been recommended for the treatment of the hæmorrhages the only one which has seemed to us to exercise any control on the loss has been belladonna, applied externally in the event of large subcutaneous hæmorrhages, or given internally in cases of bleedings from the mucous surfaces. For the notes of the cases we are indebted to Dr. G. Wilkinson, late senior house surgeon.

CASE 1.—A boy aged fifteen years was admitted to the Bolton Infirmary on Feb. 7th, 1895, with a swelling in the left hypochondriac region the result of an injury. He gave the history that he was carrying a bundle of dye-sticks when he stumbled and fell with his abdomen on the blunt end of one of them. On admission there was found to be a swelling about the size and shape of half an orange, midway between the umbilicus and the cartilage of the tenth rib on the left side. When the patient coughed the swelling enlarged. It could be put back entirely into the abdominal cavity, and when this was done a well-defined rounded opening about one and a half inches in diameter could be felt in the abdominal wall beneath the skin. The substance protruded beneath the skin when the patient coughed and had the knotted feel of omentum. The skin over a part of the swelling was superficially abraded. The patient was put to bed, carefully dieted, and a pad and bandage were applied to the seat of injury. On March 6th the subcutaneous rent in the abdominal wall had nearly closed, so that only the tip of a finger could be introduced, and the abrasion had healed. The patient was supplied with an abdominal belt with pad and was allowed to get up. On Dec. 9th the patient came up for inspection. He had resumed work and discontinued the use of the belt. There was a prominent scar marking the seat of abrasion, which showed signs of cheloid growth. The rent in the muscular layers had quite closed and firm scar tissue was felt.

CASE 2.—A boy aged eleven years was admitted on June 18th, 1894, with hæmorrhage from the cheek and gums. He gave the history that he was struck on the left cheek with a cricket bat four days before admission and that there had been continual bleeding from his gums and cheek since. His previous history was as follows. When two years of age his tongue ulcerated and bled for three weeks; at three years of age he received a wound on the back of his head, which bled during five or six weeks; when seven or eight years of age he had a wound of the temple, which bled three or four weeks in spite of plugging, caustic, &c. There was no history of any male relative having been similarly affected. A sister aged twenty-five years had had four miscarriages and a boy who died at the age of eight months. The patient had a sallow complexion with transparent condition of skin. The conjunctiva was not unusually pale and there was no heart murmur. Tincture of perchloride of iron was applied to the wound of the cheek without much beneficial effect. Finally a silk suture was introduced and proved effectual. Arsenic and tincture of perchloride of iron were given internally and the mouth was frequently washed out with iced Condy's lotion. On July 9th the wound had quite healed. On Nov. 28th, 1895, the patient was readmitted on account of hæmorrhage from a wound of the upper lip inflicted by falling against a frame eight days previously. The hæmorrhage having ceased after admission it was not thought advisable to disturb him. Free hæmorrhage, however, came on in the night, which was controlled by the introduction of a silk suture. On Dec. 23rd the wound had not healed, but was slowly granulating.

Medical Societies.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

Recent Progress in Pathology and Treatment of Diseases of Joints.—Optic Neuritis.

A MEETING of this society was held on April 10th, Mr. ERNEST CLARKE, President, being in the chair.

Mr. HOWARD MARSH read a paper on Recent Progress in Pathology and Treatment of Diseases of Joints, illustrated by specimens. 1. He discussed syphilis as affecting joints, first in children, secondly in adults. As to children, he pointed out that two forms of syphilitic disease occur—viz., a destructive lesion of the growing part of the bone, especially common in early infancy, and a gummatous infiltration of the synovial membrane affecting children between three and nine years of age frequently multiple and often symmetrical. The joint is swollen, but freely movable, which is not the case in tuberculous disease. In adults syphilis produces: (1) a simple synovitis with effusion, readily mistaken for subacute rheumatism, sprain, or commencing tubercle, but yielding readily to potassic iodide; (2) a gummatous infiltration of the sub-synovial tissue similar to Brodie's pulpy degeneration; and (3) a deep serpiginous ulceration of articular cartilage similar to and simultaneous with ulceration of soft parts and of the long bones. The treatment of the two latter groups is necessarily prolonged, and it is especially unsatisfactory in joints and rheumatic subjects. 2. The joint lesions of syringomyelia were then described and specimens shown of both the atrophic and hypertrophic forms. 3. Senile tuberculosis of joints was next discussed and its comparative frequency insisted on. The prognosis of these cases is invariably bad; the older the subject the more rapid is the downward course. 4. A very rare specimen of the effects of repeated hæmorrhages into the joints in Hæmophilia was shown. 5. Finally, Mr. Marsh showed the practical importance as regards treatment of the fact, recently ascertained, that the seat of active tuberculous disease in the joints of children is the growing tissue at the end of the diaphysis, and he urged that in children under twelve exercise is radically wrong, not touching the seat of disease. In these cases rest, begun early and maintained for prolonged periods, gives the best results. It is difficult to induce people to go on long enough. Less than fifteen to eighteen months is a farce. Some patients have been kept in leather splints for seven years to effect a cure. The principle of forcibly straightening the joint is wrong, because it is desirable to avoid interarticular pressure. The leather splints should be fitted to the limb as it is and altered as the limb gradually straightens itself, as it will do when the muscular spasm is relieved.—Mr. POLAND and Dr. TAYLOR spoke.

The PRESIDENT showed a case of Optic Neuritis following Influenza in a girl whose vision was reduced to $\frac{6}{60}$, but under potassic iodide had again become normal (both eyes $\frac{6}{6}$), while the pearly whiteness of the discs originally observed still continued.

LIVERPOOL MEDICAL INSTITUTION.

Ladies' Charity and Lying-in Hospital.—Multiple Wound of the Small Intestine and Penetration of the Gravid Uterus by a Stab.—Operative Treatment of Varicose Veins of the Lower Extremity.

A MEETING of this society was held on April 7th, Dr. WILLIAM MACFIE CAMPBELL, Vice-president, being in the chair.

Mr. MITCHELL BANKS called attention to the recent action of the committee of the Ladies' Charity and Lying-in Hospital which involved the resignation of the entire staff.—The following resolution was proposed by Mr. BANKS, seconded by Dr. CAMERON, and was carried unanimously: "The members of the Medical Institution desire to place on record their firm and unanimous protest against the course recently adopted by the managing committee of the Ladies' Charity and Lying-in Hospital, in endeavouring to place the matron-midwife in a position which practically would have vested in her the medical control of the patients. They consider that, however efficient she may be as a midwife, her want of knowledge in other respects might have caused her to overlook or fail to recognise dangerous incidental complications occurring in the course even of a so called natural labour, the timely treatment of which by a member of the medical staff might have averted serious consequences to the patient. They wish at the same time to convey to the members of the medical staff their high appreciation of the sense of duty and professional honour which actuated them in declining to retain office under conditions to which they themselves could not possibly submit, and which they believed to be detrimental to the best interests of the charity."
